thyroidism, although she may have had a mild . We have seen older people who have a degree of diabetes with hyperthyroidism. As this patient had a fairly severe diabetes, wondering if she did not have persistent thyroidism right through, which accounted for the sudden development of a severe grade of diabetes. Ordinarily, when a person has diabetes mild or severe degree and hyperthyroidism, there is practically no diabetes left after the latter is treated, so that unless diabetes had been present long time or unless the hyperthyroidism had been worse, we have to assume that the diabetes was a new development. On the story, I should think that the patient was cured so far as the hyperthyroidism was concerned and that she developed diabetes de novo. I did not see her during the last episode.

CLINICAL DIAGNOSES

Diabetic coma.
Perirectal abscesses.

DR. BUTLER'S DIAGNOSES

Perianal abscesses.
Diabetes mellitus, with acidosis.
Cellular depletion.
Cardiac failure.
Cystitis?
Glomerulonephritis?
Pyelitis?

ANATOMICAL DIAGNOSES

Diabetes mellitus.)
Diabetic coma.)
Hydropic degeneration of islets of Langerhans of pancreas.
Lymphocytic infiltration of pancreas.
Pneumonia.
Perianal abscesses.
Acute cystitis.
Pulmonary atelectasis.
Thyroiditis.)
Surgical scar: thyroidectomy.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The last basal metabolic rate three years before entry and was normal, $+2$ per cent. Autopsies on patients with diabetes, as Dr. Butler has mentioned, are usually unsatisfactory. We are rarely able to diagnose the exact cause of death. In many cases, infection is the underlying factor that puts the patient into a coma.

In this child I should think the severe perianal infection probably started the ball rolling and ended in coma. There was a lot of perianal infection at the time of autopsy, as well as scattered foci of bronchopneumonia. We were able to get a piece of thyroid tissue, which showed no

evidence of activity; the abnormal histology was perhaps due to irradiation, such as we have seen in other cases. The pancreas was about normal in size and on section showed something that I had never seen before—a fairly diffuse lymphocytic infiltration throughout the parenchyma, which for the most part did not involve the islets. Not having seen many cases of diabetes in children, I talked to Dr. Shield's Warren; he also had never seen this type of lymphocytic involvement. I believe that we have to assume that it was just the result of a mild chronic pancreatitis, because in addition to that there were numerous areas of fibrosis and destruction of the acinar tissue. The islet cells themselves were about normal in size and number, but in many there was definite hydropic degeneration, the type of change that one sees in acute, severe diabetes in children. There was also a mild cystitis and pyelitis, but no evidence of kidney disease. The glycogen stains showed what we expected to find—deposits of glycogen in Henle's tubules in the kidneys and a liver almost completely replaced by glycogen.

CASE 30452

PRESENTATION OF CASE

A sixty-two-year-old housewife entered the hospital because of severe pain in the back.

So long as she could remember, the patient had experienced low back pain radiating down the posterior aspects of both legs to the heels. The pain was intermittent and lasted for days. Occasionally it occurred after lifting or carrying heavy bundles, but this was not the rule. Six months prior to entry the pain increased in intensity and frequency and was severer in the right leg than in the left. She had frequent muscle cramps in the right leg. According to one statement the pain always started on the right side, and when severe, it was also felt in the left leg. At times the pain was severe enough to require codeine. There was paresthesia of the small toe of the right foot.

Physical examination showed a moderately obese woman who experienced severe distress on motion. The heart, lungs and abdomen were normal. There was slight tenderness in the lower lumbar region. Straight leg-raising on the right was limited to 35° and produced pain down the back of the leg to the heel. On the left it was limited to 60° , with pain down the back of the leg to the knee. Forward bending was limited, and the fingertips could be brought to within only 40 cm. of the floor. The lumbar spine was moderately flattened. Jugular compression did not cause pain. The right

was kept of the relation of the qualitative tests to the quantity of the urine. Hence, all were qualitative.

The acetone determination warrants one comment. A patient in recovery from diabetic coma should not become free of glycosuria before the ketonuria has been cleared up. The persistence of ketosis means the continuation of starvation, which is the cause of the ketosis. The ketosis is a factor in the diabetic acidosis, nausea, dehydration, and so forth. The starvation must be corrected before the ketosis can be stopped, and the only means of stopping starvation early in treatment is the administration of glucose with adequate insulin. Hence, enough glucose should be given so that the urine does not become sugar free until the ketosis has stopped.

"During the first six hours she received intravenously 4500 cc. of a solution consisting of two-thirds isotonic saline solution and one-third 1/6 molar sodium lactate solution, as well as 250 cc. of plasma." That solution, in my estimation, is the correct solution to give in the early stage of repairing the extracellular fluid loss in diabetic coma.¹ The concentration of sodium chloride and lactate (or potential bicarbonate) in such a mixture prevents the continuation of the acidosis while hydrating a patient who is so dehydrated that the kidneys will not function correctly. If one gives physiologic saline solution instead of this combination of two solutions one is administering a solution that, in terms of serum, is hypertonic in chloride by 50 milliequiv. per liter.¹ Physiologic saline solution also has no bicarbonate. The result of giving physiologic saline solution to a patient whose kidneys are handicapped by the poor blood flow incident to dehydration is an elevation of serum chloride and a continuation of the acidosis. To continue for hours the Kussmaul breathing and resultant muscular exertion in a diabetic patient who has suffered severe starvation, severe dehydration and severe cardiac and circulatory embarrassment is not good therapy. The particular combination of sodium lactate and saline solutions is good because it provides an approximately normal plasma chloride concentration — 100 milliequiv. per liter — and a bicarbonate or potential bicarbonate (according to whether one uses sodium bicarbonate or sodium lactate) concentration of approximately 50 milliequiv. per liter, which is double the normal. So immediately there begins a correction of the alkalosis; almost immediately the respirations improve, and in an hour they will be rather markedly improved. Such an infusion cannot do harm. If it puts the patient to rest, it must be good. As soon as the respirations are eased, physiologic saline solution can be used in place of the combined solution.

I am not sure that the disappearance of sugar from the urine meant that the blood sugar had returned to normal, for this patient may have had

renal disease and a hyperglycemia without glycosuria. Whether or not she had renal disease, I should have favored using intravenous glucose after a couple of hours of hydration therapy, since the maintenance of hyperglycemia favors the utilization of glucose and starvation can be stopped only if there is a utilization of glucose. The work of Mirsky² shows that hyperglycemia improves the utilization of glucose. There is no evidence that maintaining the blood sugar above normal does harm provided that something is done about hydrating the patient and that the urine volume is adequate, as it was in this patient. Thus, after two hours of therapy 5 per cent glucose might have been started intravenously, later increasing the glucose to 10 per cent and using insulin in liberal doses while giving the glucose. Glucose administered beyond the rate of immediate oxidative utilization builds up the depleted glycogen stores. Unless this is done, the high blood sugar and the ketosis are difficult to control.

There were no signs or symptoms of pulmonary edema or cardiac failure during the parenteral therapy, since the rate and volume were not excessive.¹ Yet this patient died in the same manner that patients with diabetes sometimes do; that is, after considerable hours of therapy and improvement, they suddenly fail rapidly and die. Analyses show that the serum sodium, chloride and carbon dioxide and the blood sugar were satisfactory. The urine sugar and ketosis had cleared up. Yet she died. I do not know why, but possibly Dr. Castleman can tell us. In this particular case a renal infection or a pre-existing nephritis may have been a factor. Because there is no record of urine cultures and nonprotein nitrogen determinations and because of the presence of perianal infection I do not know whether there was renal infection or nephritis.

In the interest of possibly improving the treatment of such patients, attention should be called to the fact that for sixteen hours this starving patient was given nothing but water, sodium chloride, glucose and insulin, with the exception of a few ounces of meat broth. Extracellular fluid and a total of only 100 gm. of glucose, providing 400 calories, were given this depleted patient. Possibly another 90 gm. of glucose from the body was oxidized to provide an additional 360 calories, but no intracellular constituents were given with these 760 calories to provide for cellular activity or repair. Such is the custom. It ignores the fact that extracellular repair does not restore intracellular depletion, nor does it provide substances essential to the life of cells and patients.

DR. BENJAMIN CASTLEMAN: Dr. Lerman, would you like to say something about the relation of diabetes to exophthalmic goiter.

DR. JACOB LERMAN: Presumably this child did not have diabetes at the time she was treated for

DR. SAMUEL LOWIS: The fact that the patient had pain on lumbar puncture at two different levels favors tumor rather than a ruptured disk. Furthermore, a ruptured disk would not be so large as this lesion.

CLINICAL DIAGNOSIS

Ruptured intervertebral disk?
Tumor of cauda equina?

DR. MICHELSEN'S DIAGNOSIS

Neurofibroma of cauda equina?
Ependymoma of cauda equina?

ANATOMICAL DIAGNOSIS

Neurofibroma of cauda equina.

PATHOLOGICAL DISCUSSION

DR. KUBIK: Dr. W. J. Mixter operated on this patient. He started out by taking off the lamina of the fourth vertebra and came down on a tumor beneath the dura. The tumor, which was found to extend from the lower margin of the lamina of the second lumbar vertebra to the upper margin of the lamina of the fifth lumbar vertebra, was removed except for small bits that were adherent to one or two of the spinal nerves of the cauda equina. Histologically it was a neurofibroma.

The patient made a good recovery, but still has some pain. It is rather interesting, considering the large size of the tumor, that the abnormal neurologic findings were not pronounced, but this is not unusual. We have had cases of both neurofibroma and ependymoma in that locality with no abnormal neurologic findings.

ankle jerk was absent, but the neurologic examination was otherwise negative.

The blood pressure was 150 systolic, 90 diastolic. The temperature, pulse and respirations were normal.

Examination of the blood showed a white-cell count of 8500. The urine was normal. A blood Hinton test was negative.

Anteroposterior and lateral films of the lumbar spine showed flattening of the lumbar curve and a list to the left between the fourth and fifth lumbar vertebrae. The interspace between these vertebrae was markedly narrowed, and there were degenerative changes at this level and between the fifth lumbar vertebra and the sacrum, with increased density of the margins of the vertebral bodies.

Lumbar punctures at the third and second interspinous spaces caused unusually severe pain. Only a few drops of spinal fluid were obtained. Because of the pain further attempts at lumbar puncture were not made.

On the sixth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. JOST MICHELSEN: At first glance this seems to be a story of a ruptured intervertebral disk in the lower lumbar region on the right side. For many years the patient had intermittent pain low in the back and in both legs, more so on the right side. The pain was severe and was exaggerated by certain activities. It occurred after lifting or carrying bundles. It was associated with paresthesia of the small toe on the right. There was limitation in forward bending. The lumbar spine was flattened. The right ankle jerk was absent. All these facts are consistent with a ruptured disk in the lower lumbar region.

I shall disregard the x-ray findings of narrowing of the fourth lumbar interspace. It may be found as an incidental observation in patients with no symptoms. The evidence of proliferative changes at the fourth and fifth interspaces is also of little significance for the diagnosis of the level of the lesion.

The paresthesia of the right small toe and the absence of the right ankle jerk indicate that the right first sacral posterior nerve root was involved. Consequently, if the lesion was a ruptured disk it was a protrusion at the lumbosacral interspace on the right side.

The question arises whether this was a ruptured disk. For several reasons I have a notion that it was not. I am inclined to believe that the severe pain that was observed during the lumbar puncture and the fact that only a few drops of cerebrospinal fluid were obtained are significant. I assume, of course, that the lumbar puncture was well executed. The pain, as well as the small amount of

fluid, suggests that there was an intradural mass. On reviewing the history with this possibility in mind one gets the impression that the pain that the patient had had for so many years was not of true mechanical nature. It is said that occasionally it occurred after lifting or carrying heavy bundles, but that this was not the rule. Intermittent spells of pain lasting for only a few days would also be somewhat unusual for a ruptured disk. This is all I have to go on, however, when I suggest the possibility that the lesion was an intraspinal neoplasm.

If there was a tumor, I presume that it had been present for a long time. This is against a malignant lesion. Of other lesions, I should consider neurofibroma, meningioma and ependymoma. Meningiomas in the lumbar area are extremely rare, and I have never heard of one in this area. Ependymomas frequently occur in the cauda equina region. With the long duration of symptoms, however, one would expect widening of the spinal canal, destruction of the pedicles and erosion of the posterior portion of the vertebral bodies at the site of the lesion and probably definite signs of compression of the cauda equina. This leaves us with the third possibility, which is the likeliest. Neurofibromas are the most frequent of the neoplasms of the spinal canal. These nerve-sheath tumors vary in size. It is possible that the tumor originated from the first sacral posterior root on the right and expanded slowly to produce the cerebrospinal-fluid disturbances and displacement of nerve roots, which led to the difficulties that were encountered on lumbar puncture.

I admit that I am unable to make a definite diagnosis of the type of the lesion and only an approximate diagnosis of its true seat. I believe that the patient had an intraspinal lesion in the lumbar area, either a large ruptured disk at the lumbosacral interspace or an intradural neoplasm in the region of the cauda equina. I favor the diagnosis of a neoplasm, either an ependymoma or, likelier, a neurofibroma.

DR. AUGUSTUS S. ROSE: I was wondering if the absence of sphincter difficulty is of any significance.

DR. MICHELSEN: As I tried to point out, it is particularly against an ependymoma. The lesion was probably a neurofibroma.

DR. JAMES B. AYER: Is the absence of sensory findings against neurofibroma?

DR. MICHELSEN: The fact that the only sensory disturbance was a paresthesia of the right little toe is extremely significant.

DR. CHARLES S. KUBIK: Paresthesias are of no assistance in diagnosing the nature of the lesion, but they do help to localize it.

DR. MICHELSEN: That is correct.

DR. AYER: I admit that it is possible for a large ruptured disk lying in the canal to cause paresthesia.

in this country, on methods for controlling such infections. Particular attention has been paid to borne infections and their control with the use of aviolet light and germicidal aerosols.

In 1939, the Preventive Medicine Committee of the Medical Research Council of Great Britain appointed the Subcommittee on Cross Infections in Hospital Wards. This committee* has just published an abbreviated report that contains practical suggestions for civilian hospitals in wartime Britain. It may well serve as a guide for use in hospitals everywhere, as well as for the planning of improvements in hospitals or in the construction of new hospitals during the postwar period.

In a foreword to this report, Sir W. Wilson Wilson, the British Minister of Health, points out the great and steady drain that cross infections make on hospital finances and efficiency. Overhead expenses continue and admissions are delayed while the wards are kept in quarantine. Patients who are detained on account of intercurrent diseases may even die and are, in any case, a continuing source of expense and anxiety. For these reasons, requests for improvements and equipment calculated to lessen the risk of such infections should receive careful attention. When new construction is contemplated, the prevention of cross infection should be an over-riding consideration, and expert advice should be sought.

The report outlines in adequate detail the sources and modes of infection, and indicates in a practical way how these actually come about in practice. Particular attention is called to the great increase in bacterial counts in the air of hospital wards during sweeping and bedmaking. The methods of preventing and controlling cross infection are given in considerable detail, including general administrative procedures, those for admitting patients and methods of isolation nursing. The problem of hemoprophylaxis is considered. The role of ward attendants and ways of minimizing infection from this

source, as well as from the medical and hospital personnel, are given appropriate attention.

Many forms of labor-saving devices are mentioned. Simple methods for the control of contact and mediate infection are enumerated. These include washing of the hands, care of laundry, preparation of food, proper care in taking temperatures and in the handling of children's playthings and a technic for surgical dressings. The problem of controlling droplet-borne and dust-borne infections is also considered from the point of view of ventilation, bed spacing and the use of face masks and aerial disinfectants. Methods are outlined for the treatment of bedclothes and that of ward floors with spindle oil or another suitable oil in such a manner as to reduce or to eliminate dust.

An entire section is devoted to the procedures to follow on the occurrence of cross infection in a ward. Detailed methods are given for discovering the source and the mode of spread, attention being given to individual diseases, such as hemolytic streptococcus infections, measles, enteric infections, chicken pox and gonococcal vulvovaginitis.

At the end of the memorandum is an appendix containing an outline of details concerning disinfection and sterilization. A second appendix gives practical rules for isolation nursing in cubicles or on open wards. Others outline special precautions for maternity units, rules for ward dressing teams and methods of applying dust-preventing oils. Finally, there is an appendix outlining a course of practical bacteriology for nurses, with suggestions for demonstrations and practical work for the instruction of all interested personnel in the part they must play in preventing cross infection.

All the subject matter outlined is contained in twenty-eight pages of text. Every physician and administrator who is responsible for the care of hospitalized patients can readily profit by reading and studying this brief memorandum. The details are also well adapted for use in the teaching of nurses in training schools. Furthermore, graduate nurses who are responsible for the care of patients in hospitals will profit by acquainting themselves with the contents of this memorandum.

**The Control of Cross Infection in Hospitals*. Memorandum prepared by the Committee on Preventive Medicine of the Medical Research Council the Sub-Committee on Cross Infections in Hospital Wards. Medical Research Council, War Memo. No. 11, 34 pp. London. His Majesty's Stationery Office, 1944.

UNITED WAR FUND

Now in full swing, the Greater Boston United War Fund campaign reflects the will of a great community working together for the common good. Before Thanksgiving Eve, \$7,650,000 must be raised to meet the 1945 needs of home-front and fighting-front services.

Year in and year out, services here at home are adding new and tangible meaning to the words, "Life, Liberty and the Pursuit of Happiness." Throughout the world, the war services are giving convincing proof of their worth. United Nations Relief provides food, shelter and medical supplies to sixteen allied countries — Belgium, Great Britain,

Czechoslovakia, Denmark, France, Luxembourg, Greece, Italy, Lithuania, Norway, Holland, the Philippines, Poland, Russia, China and Yugoslavia. Refugee Relief Trustees helps refugees of war-torn countries until they become integrated and contributing members of a free society. The United States Committee for the Care of European Children brings youngsters to this country from ravaged countries and undertakes their care while they are here.

"Show That You Care" is this year's campaign cry. Physicians have always cared, serving rich and poor alike. And they, because they are physicians, understand better than others the harmful results of malnutrition in occupied countries and the deteriorating effect of the war prisoner's life. Knowing so well what is at stake, they should give generously and wear their Red Feathers with pride.

THE CONTROL OF CROSS INFECTIONS IN HOSPITALS

THE modern treatment of many severe diseases often requires elaborate methods of diagnosis and many forms of therapy, which are difficult to carry out in the home. Most hospitals are provided with the necessary facilities and with properly trained personnel for these diagnostic and therapeutic measures. The fact, however, that many people sick with various infectious diseases are brought together in the same wards and buildings carries with it the risk that patients will acquire infection that they did not have on admission and that they would not have acquired if treated at home. The greatest risk of cross infection is, of course, in infants' and children's wards, where sources of infection are always present. With adults, there is considerable risk for those with wounds and burns and for women in the puerperium.

The last decade has seen great advances in the study of such infections. The ability to identify specific types of pneumococci and streptococci has made possible the tracing of cross infections due to these organisms. More recently, extensive studies have been carried out, particularly in Great Britain

it is, does not begin to indicate the real reasons Doctor Breed's conspicuous success in the practice of medicine and in the art of living. His sincere unflagging interest in people, his patient understanding and his gift for friendship are attested to by a host of devoted patients and friends—these hardly be separated, since so many of his patients became his friends, and so many of his friends his patients. As the late Professor Hanser wrote of him in the autobiography *As I remember Him*, "... [he] was one of those precious individuals whom nature had meant to be physicians."

certain significant factors in his life cannot be dissociated from his complete personality: his devotion to his home and family, after those years when he had had so little of either; his love of music—he was once rated by Philip Hale as the amateur violinist in Boston; and his interest in fishing—he was a lover of little rivers and of lakes and ripples.

Let this be taken as a tribute to his particular genius, that to his friends he is still a present, a vibrant reality, to be found at the Tavern Club with his violin, or encountered in the corridors of the Massachusetts General Hospital, or met upon a rocky beach of Moosehead Lake. If remembrance of some part of immortality, then that part of mortality is assured.

"They have not gone, nor can they dwell apart
Who still hold place within some human heart."

J. G.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

BLAISDELL—J. Harper Blaisdell, M.D., of Winchester, died October 25. He was in his fifty-ninth year.

Dr. Blaisdell received his degree from Harvard Medical School in 1911. He limited his practice to dermatology and fought for many years at the Harvard Medical School. He was a member of the staffs of the Massachusetts General Hospital and the Boston Dispensary and served as consulting dermatologist for several other hospitals. He was a member of the American Medical Association, the American Dermatological Association and the Atlantic Dermatological Conference. He was past president of the New England Dermatological Society and, at one time, chairman of the Section of Dermatology and Syphilis of the American Medical Association. He had long been prominent in the affairs of the Massachusetts Medical Society, and was one of the time movers in the organization and administration of the Blue Cross and the Blue Shield.

His widow and two sons survive.

CHRISTIERNIN—Charles L. Christiernin, M.D., of Maplewood, New Jersey, died October 18. He was in his sixty-seventh year.

Dr. Christiernin received his degree from Harvard Medical School in 1906. At the time of his death he was medical director of the Metropolitan Life Insurance Company of New York. He was active in the medical societies of the United States and Canada, and was well and favorably known in both life-insurance and health circles in the two countries. He had served as treasurer, vice-president and resident and as a member of the Executive Committee of the Association of Life Insurance Medical Directors. He was a member of the American Medical Association.

His widow and two sons survive.

FENWICK—George B. Fenwick, M.D., of Chelsea, died October 27. He was in his sixty-eighth year.

Dr. Fenwick received his degree from Harvard Medical School in 1904. He was a member of the local Selective Service board and had organized the medical unit of the Massachusetts Committee on Public Safety in Chelsea.

His widow, a daughter and a son survive.

MARSHALL—Commander John R. Marshall (MC), U.S.N.R., of Somerville, died October 14 at the United States Naval Hospital at Shoemaker, California, where he was stationed as a surgeon. He was in his fifty-seventh year.

Dr. Marshall received his degree from Harvard Medical School in 1918. He was a staff member of the Cambridge Hospital, the Symmes Arlington Hospital and the Lawrence Memorial Hospital and had formerly served at the Mayo Clinic. He was a member of the American Medical Association and a fellow of the American College of Surgeons.

His widow, a daughter and two sons survive.

SHAW—Albert J. Shaw, M.D., of Newton, died May 23. He was in his seventy-third year.

Dr. Shaw received his degree from Harvard Medical School in 1894. He was a member of the American Medical Association.

His widow survives.

SIMS—Frederick R. Sims, M.D., of Northampton, died October 26. He was in his sixty-sixth year.

Dr. Sims received his degree from Harvard Medical School in 1902. He served in the state hospitals at Danvers and at Taunton before going overseas as a major in the Medical Corps in World War I. He was chief medical officer at the Bedford Veterans Hospital from 1934 to 1937. At the time of his death he was psychiatrist and retired chief medical officer of the United States Veterans Administration Facility in Northampton. He was a member of the New England and the American psychiatric societies.

His widow, a son, a brother and a sister survive.

CORRESPONDENCE

DEPRIVATION OF LICENSES

To the Editor: At a meeting of the Board of Registration in Medicine held October 18, the Board voted to revoke the license of Dr. Robert E. Conlin, 18 Auburn Street, Woburn, to practice medicine because of gross misconduct in the practice of his profession as shown by his conviction in court and treatment of a patient.

TRANSFUSION ACCIDENTS

To the Editor: In the December 8, 1938, issue of the *Journal* you were kind enough to publish my letter concerning a series of severe transfusion accidents in all of which the patients had died following the administration of incompatible blood. Since then, it has been my misfortune to have seen an increasing number of similar cases. Although I have often commented on them both in writing and at lectures, it seems wise at this time to make the following suggestions:

Give whole blood only if it is *urgently* indicated, and not simply as a "boost" or because it is readily available from a blood bank. Too many transfusions, particularly now that blood banks have been established in a large number of hospitals, are being given as a more or less routine measure in surgical operations. Indications for the use of whole blood are relatively few.

OBITUARY

WILLIAM BRADLEY BREED
1893-1944

"When a man becomes dear to me,
I have touched the goal of fortune."

William Bradley Breed was born in Syracuse, New York, the younger son of a physician. He lost his father when a child, and after the death of the brother, his mother took him to Germany for a year, where he continued his education and studied the violin. He later graduated from the Hackley School in Tarrytown-on-the-Hudson. When he entered Harvard College in 1911, his mother established herself in Cambridge, remaining there until her death, while he was still an undergraduate.

During his college years he continued to show an interest in music; he was a member of the University Musical Clubs and leader of the University Mandolin Club. He had membership also in Delta Upsilon, the Speakers' Club and the Deutscher Verein. At the Harvard Medical School, from which he graduated with the class of 1919, he was a member of the Boylston Medical Society, Phi Rho Sigma, the Aesculapian Club and the Stork Club.

In 1918 and 1919 Doctor Breed served as medical intern in the Massachusetts General Hospital; the following year he held a residency at the New England Deaconess Hospital, later establishing himself in the practice of internal medicine in Boston.

He was married in 1925 to Ruth Williams, of Dedham, who survives him, with their three children, Elizabeth, Sylvia and William.

The posts that he occupied and the positions of trust that he held are ample evidence of the esteem

in which he was held by his professional colleagues. For the greater part of his active medical career he was on the staff of the Massachusetts General Hospital, receiving his final appointment as physician in 1936, the same year in which he became member of the General Executive Committee. In that year, also, he was appointed associate in medicine at the Harvard Medical School.

From 1925 until 1936 he was visiting physician

to the House of the Good Samaritan, joining its honorary staff in the latter year. He was physician at St. Luke's Hospital and a member of the staff by the courtesy of the New England Baptist, the New England Deaconess, the Faulkner and the Robert Breck Brigham hospitals. He became an associate editor of the *Journal*, then the *Boston Medical and Surgical Journal*, 1923, retiring from the less active editorial board in 1937. In 1942 he was appointed to the Committee on Publications of the Massachusetts Medical Society.

For a number of years Doctor Breed was a member of the Council of the Society, and in 1943 and 1944 he served as chairman of the

Participation Committee. He was a member of the New England Heart Association, the American Clinical and Climatological Society and the American College of Physicians. In the American College of Physicians he had been governor for Massachusetts since 1935 and chairman of the Board of Governors since 1942, also being a member of the Committee on Credentials and a member *ex officio* of the Board of Regents.

His published articles appeared in the *Boston Medical and Surgical Journal*, the *New England Journal of Medicine* and the *Annals of Internal Medicine*.

Such a list of positions held and of varied contributions to medical progress, however outstanding,

POSTWAR PLANNING IN ANESTHESIOLOGY*

HENRY S. RUTH, M.D.†

PHILADELPHIA

ANESTHESIOLOGY has now established its unequivocal value to the surgical and medical professions, and to those seeking medical care coming under its jurisdiction. The inherent dynamic nature of the specialty with its present broad application was gaining momentum rapidly during the immediate prewar period. Its increasing sphere of application was being affected less and less in those years by specious economic opposition and examples of personal and institutional obstacles. A permanent retardation of its growth because of the temporary cessation of its activities in civilian life engendered during the war is therefore not expected. Conversely, growth may be further stimulated in the postwar period because of its wartime contributions and experiences. Thoughtful guidance and planning are indicated, however. The statements and proposals suggested here spring from an attempt to project into the future the trends exhibited by anesthesiology as observed during the past twenty years, coupled with the possible effects of the impact of a sudden peace following total war.

Postwar planning is a vitally important problem at this time. The details of proposals for the management of the initial peace period should, however, as yet remain flexible. This country has lived the period where the major issue of victory or defeat was not clear, but its people are still ignorant of the element of time required for victory, its ultimate cost from numerous angles and the sociologic conditions that will be present thereafter. Many authorities believe that postwar medical practices will undergo a metamorphosis of a type as yet undetermined. Some believe that the very structure of modern medicine may be altered. If such future attempts at outside control are successful, the younger specialties may be affected first. Those within the specialty should look forward to future progress for many reasons, one of which will be outlined, irrespective of possible future changes in medical practice. It is

believed, also, that there will be the continued active support of a growing portion of the medical profession in the future, as now.

The first problem of postwar medical planning naturally concerns the return to civil life of medical men in military service. For anesthesiology, these may be logically and conveniently grouped in three classifications. The first comprises the adequately trained, fully experienced anesthesiologists. Some members of this group were professors in universities and directors of anesthesia in large hospitals, in situations in which they could contribute to both instruction and medical service, according to their qualifications. Without doubt, the greater number of these positions will be awaiting the former incumbents on their return, to the mutual satisfaction of both institutions and teachers. A few may seek new positions for many reasons, and for these replacement will be indicated. A proposed plan for the relocation of these persons will be discussed.

When the present war began, the importance of anesthesiologists was recognized by the armed forces, and courses of instruction for medical officers in both military and civilian hospitals were initiated. In this way, material numbers of men received their basic training in anesthesia. It is the general belief that most of the officers so trained, who comprise the second group, will continue in the specialty after the war; for example, the majority of the men thus trained in Philadelphia expressed such a desire both during training and thereafter. A portion of these officers will have received sufficient additional training or supervised experiences to enable them to practice immediately on discharge. The same will be true of men who had just completed their formal training at the outbreak of the war and immediately entered the Service, with no opportunity for civil practice. This group will also desire aid in suitably locating themselves.

The third group is composed of men who require additional training. A portion of them will consist of those medical officers who were hurriedly and

*Presented at the annual meeting of the Massachusetts Medical Society, Boston, May 24, 1944.

†Professor of anesthesiology and head of the Section on Anesthesiology, Jefferson Medical College and Hospital

If, after due consideration, it is believed that whole blood and not plasma or fluids should be given, it is imperative:

To type both the patient and the donor with high-titer serums.

To retype banked donor blood before use even if it has already been labeled.

To cross match the donor's cells with the recipient's serum. This should be done by the Landsteiner-Levine test-tube technic, the slide cross-matching technic often being unreliable.

To have the results of the cross match checked either by an experienced technician or by an experienced physician. Reliance on inexperienced personnel for something as inherently important as a blood-grouping test may, and often does, result tragically. Unfortunately it appears to be a frequent practice to entrust blood-typing and cross-matching procedures to the lowliest intern or the newest technician.

If the above procedures have been carried out the transfusion may be started. During administration of the first 50 to 100 cc., the patient should be carefully observed by an experienced observer. Any complaint of pain in the flanks, of a sense of constriction in the chest or even of a "queer" feeling should be carefully heeded and the transfusion should be immediately stopped. This requires a wide-awake patient who can feel pain and other sensations and precludes the use of transfusions during both general and spinal anesthesia. If the first 50 to 100 cc. of blood go in without reaction, it is reasonably safe to assume that the blood is compatible and that the cross match has been satisfactorily performed. *This in vivo test is of utmost importance and should never be ignored.* It is often lifesaving, since the recipient can take perhaps up to 100 cc. of incompatible blood without too much difficulty, whereas more than that amount results in an irreversible agglutination of red cells within the circulation and the renal glomeruli and in the deposition of hematin plugs within the tubules. The end-results of such a severe reaction—aside from hemoglobinuria and hemolytic anemia—are renal failure, azotemia and almost always death. No amount of fluids, alkalies, hypertonic solutions and so forth can modify this essentially mechanical nephropathy, in which the glomeruli and tubules are largely blocked and functionless.

If the patient is pregnant or has been delivered, or if more than one transfusion is contemplated, an Rh determination should be performed in addition to the regular blood-grouping tests. If good anti-Rh testing serum is not available, an exceedingly careful cross match (test-tube technic) should be performed, and the in vivo reaction carefully watched.

As I have repeatedly stated, these severe transfusion reactions of incompatibility are by no means scarce. I have seen many of them, but few are reported. Their essential tragedy becomes greatly enhanced when it is realized, too late, that the transfusion was not essential and could well have been omitted.

The following conclusions may be made:

Too many transfusions of whole blood are being given, often without sufficient indication.

Typing and cross-matching procedures should at least be checked, if not completely performed, by thoroughly trained and competent personnel, using the best available methods.

Whole blood should not be given to a patient while under the influence of a general or spinal anesthetic.

The patient should be carefully watched during the administration of the first 50 to 100 cc. of blood, and the transfusion should be immediately discontinued in the presence of a reaction, however slight.

The severe transfusion reaction is best treated by its prevention.

Prevention may be facilitated by standardization of technic, methods of administration and so forth. This might well be placed under the purview of a committee of the Massachusetts Medical Society.

WILLIAM DAMESHEK, M.D.

NOTICES

HARVARD MEDICAL SOCIETY

It has been decided to renew the meetings of the Harvard Medical Society, which were discontinued at the beginning of the war. The first meeting will be held at 8:15 November 14, in the Amphitheater of the Peter Bent Brigham Hospital. Subsequent meetings are scheduled for the Tuesday evening of each month. Each meeting will with the presentation of a clinical case with discussion followed by three papers of fifteen minutes' duration and a five-minute discussion of each paper. Arrangements have been made for the publication of reports of these meetings in the *Journal*.

Under this plan it will be possible to present clinical studies as well as the results of fundamental investigations. This should afford an opportunity for the student, the faculty and the interested medical profession to be in touch with the many studies now being carried on in different departments of the Harvard Medical School and its associated teaching hospitals.

NEW ENGLAND OPHTHALMOLOGICAL SOCIETY

A meeting of the New England Ophthalmological Society will be held at the Massachusetts Eye and Ear Infirmary 243 Charles Street, Boston, on Tuesday, November 14, at 8 p.m.

Following the business meeting, Miss Anita B. L. Giaracine will speak on the topic "Bacteriological Observations." A symposium "Some Nonsyphilitic Interstitial Lesions of the Cornea" will then be presented by Drs. C. Verhoeff, Lahey and Cogan. This will be followed by a "Preliminary Report on Bilateral Surgery in Alternating Strabismus" by Drs. Lemoine and Moore, and Miss Alice S.

SUFFOLK DISTRICT MEDICAL SOCIETY

The fall dinner of the Suffolk District Medical Society will be held on Saturday, November 18, at the Harvard Club of Boston, 374 Commonwealth Avenue, Boston. A session beginning at 6:00 p.m. will be followed by dinner at Harvard Hall at 7:15. His Excellency, Leverett Saltonstall, will speak on the topic, "Medical Social Security and Dr. Roger I. Lee on 'Health Insurance?'"

It is urged that doctors bring their wives and particularly that the wives of all doctors absent in the service, who are not the doctor is a member of Suffolk Society, be invited by members as their guests. Each member who sends the treasurer with his own application the names of service wives will receive free tickets for them. The tickets \$3.00 each, must be purchased in advance by sending a check to the treasurer, Dr. Richard S. Eustis, 319 L Street, Wood Avenue, Boston 15. Other members of the Massachusetts Medical Society may apply after November 8.

UROLOGY AWARD

The American Urological Association offers an award "not to exceed \$500" for an essay (or essays) on the result of some specific clinical or laboratory research in urology. The amount of the prize is based on the merit of the work presented, and if the Committee on Scientific Research deem none of the offerings worthy, no award will be made. Competitors shall be limited to residents in urology in recognized hospitals and to urologists who have been in such specific practice for not more than five years. All interested should write to the secretary for full particulars.

The selected essay (or essays) will appear on the program of the forthcoming June meeting of the American Urological Association.

Essays must be in the hands of the secretary, Dr. Theodor D. Moore, 899 Madison Avenue, Memphis, Tennessee, on or before March 15, 1945.

one physician anesthetist, and that it would require many years to change over to the status in which all anesthetics would be administered by physicians, even though such a thought might be accepted. On the other hand, it is also true that there are many large hospitals that could utilize the services of a number of physician anesthetists. I believe that a hospital of 125 to 150 beds can support adequately one anesthesiologist, with 100 per cent of his time devoted to anesthesiology.

It is not unlikely that experiences encountered during the present war will greatly increase the opportunity for anesthesiology. Before the war, large numbers of surgeons had never had the experience of operating under conditions provided by the physician anesthetist. Many of them had never attempted to acquire the services of a physician for anesthesia. They could, therefore, through personal experience, have no basis for a comparison of the operating conditions provided by the two types. Many of these surgeons have made or will make their first contacts with competent anesthesiologists in the armed forces and work under the improved conditions provided by them. After such an experience, it is to be seriously doubted whether many of them will be content on their return to civilian practice to retrogress to the inferior type of unsupervised technician anesthesia, where, as the law requires, they must assume full responsibility for the anesthesia, even though fully occupied with the technical requirements of the surgery, and at the same time must dictate treatment and supportive measures during the operative period. On the other hand, there will be numerous surgeons who have long been accustomed to the advantages provided by anesthesiologists who will be exposed to the nonprofessional type of service. It may be assumed that a large portion of this latter group will become even more active in furthering the advance of anesthesiology after the war.

From the viewpoint of war itself, facilities for the training of anesthesiologists should be enlarged. Disturbing though it may be, the possibility of a third world war has already been discussed by reputable international authorities. With this thought in mind, plans should now be laid in order that greater numbers of anesthesiologists may be available than existed at the outbreak of World War II. Recent experiences in the combat areas have indicated that the presence of qualified anesthesiologists at the immediate front under actual fire is quite valuable. Nurses cannot be assigned to such duties, and at the present time there are not sufficient numbers of experienced physicians for this purpose.

Some hospitals, because of the shortage of technician anesthetists, have attempted to locate physician anesthetists during this war period. They quickly learned that the shortage of physicians is more acute than that of technicians. In the post-

war period, these same hospitals should be stimulated to seek again the services of physicians. By doing so, they could probably avoid future inadequate anesthesia service. An example may be cited by comparing two large general hospitals in the same city. Hospital A for many years has had physician anesthetists, and, for the last fifteen years, residents in training. Hospital B formerly had only technicians, and placed a qualified anesthesiologist in charge only after the war had begun. Hospital A, although contributing its comparative share of personnel to the war effort, has so far provided adequate anesthesiologic care, partly because physicians usually consent to work longer hours. Also, more work has been placed on the older staff members. Although reduced 50 per cent in number of residents by the Procurement and Assignment Service, it was able to attract some of the military unit as assistants because it was well established as a training center. Hospital B, with no residents as a standard practice, could, of course, obtain no resident in anesthesiology under Procurement and Assignment Service. A large number of technicians were sent to the armed forces, and because their number could not be expanded, it became necessary to rely on interns with no experience in anesthesia. Since it is impossible for the single anesthesiologist to supervise all the work, the anesthesia service has been markedly impaired. If Hospital B had initiated this service in the prewar period, the Procurement and Assignment Service would have allowed it 50 per cent of its former residents under the 9-9-9 program and the remaining physicians would have worked longer hours with the result that the hospital would have been able to supply its share of trained men for the armed forces and that the civilian population patronizing the hospital would not have suffered anesthesia service of lowered quality.

This discussion will be concluded by a consideration of the economics of the specialty. The transition from fees collected by the hospital for the services of a technician with a short and inexpensive period of training to that of a fair fee for a physician commensurate with his ability and prolonged and expensive training is a difficult one. Attempts have been and will continue to be made to enlist the services of physician anesthetists at full-time salaries at a level only slightly above that allotted for technicians. A great error will be committed if the medical profession allows these attempts to be successful. It is only just that a physician should expect recompense commensurate with his ability and intelligence, his training and the value of service rendered. If anesthesiologists cannot expect a financial return comparable to other specialties, the desirable type of young physician will little desire to enter or remain in the field. It is here, also, that practitioners of the surgical specialties can contribute wisely by their support. It has been

incompletely trained for the emergency and were able to provide the needed service in the combat forces, but because of the incomplete nature of their preparation should be discouraged from entering civilian practice without completing their formal training. Plans should be made for sufficient suitable residencies to provide this training. The same is true of those whose interest in anesthesia has been stimulated for the first time by the war, either by observing the efficient application of modern anesthetic practices or witnessing at first hand the effects of its mismanagement in remote corners of the world, or through recognition of the opportunities offered to young physicians by the practice of anesthesiology.

It appears that some medium should be set up for the collection and filing of data concerning opportunities for the returning qualified anesthesiologists.¹ It may be that the American Society of Anesthetists might best serve this purpose. Dr. Paul M. Wood, of New York City, the present chairman of the Professional Relations Committee of the society, has stated that his committee is willing to serve in this capacity. Institutions desiring to establish contact with qualified physicians could file their specific requirements, the opportunities for service offered and the economic features, together with other essential information, with this committee. Discharged officers would then have these data available and be able to locate themselves easily and satisfactorily, with little lost time and effort.

For officers requiring graduate study in anesthesiology, additional training facilities should be provided through increasing the number of available residencies. According to the most recent published statistics, only forty-three vacancies are now offered by existing approved residencies, assistant residencies and fellowships for this type of training.² It has been estimated that should the war end by 1945, as many as 20,000 physicians will be released from military service who have never had the opportunity of beginning the private practice of medicine.³ So many will seek residencies that it is believed that 13,000 residencies will be required, whereas only 5500 are available under normal conditions.⁴ By these figures, some idea is conveyed of the proportionate increase of residencies in anesthesiology that may be required.

It seems that the postwar period would be an appropriate time to stimulate training facilities not only in quantity but also in quality. The selection of men for training should be carried out with great care. Since the specialty has expanded its activities, the mental requirements for its application have likewise increased. Residencies that are set up for the mere purpose of providing clinical anesthesia for surgical patients with unqualified or no supervision must be discontinued. A definite plan of instruction in charge of capable

physicians is necessary, and this plan must be summated efficiently. The clinical work should be under constant adequate supervision. Clinical training should include instruction and experience in all types and methods of anesthesia. The days are past when a physician could call himself anesthesiologist only because of his ability with inhalation agents and technics. It is true that thorough knowledge of physiology, pharmacology and other basic sciences is required to administer anesthetic agents by inhalation technics with greatest safety and efficiency, but spinal, intravenous and regional technics are too valuable to be lightly treated or ignored. Gas therapy, for example, the correct administration of oxygen and helium, — diagnostic, prognostic and therapeutic nerve blocks and resuscitative procedures are important aspects of training. Training in bronchoscopic technic for postoperative aspiration of air passages is quite valuable. In some institutions the management and direction of blood and plasma banks and transfusions are demanded of the anesthesiologist. Unless the above aspects of anesthesiology are included, residencies in anesthesiology can be made a mere sham for the economic well-being of the institution where they are offered.

From recent personal experience in Philadelphia, I believe that the exchange of senior residents between institutions offering training is invaluable from all aspects. In addition to broadening the experiences of the residents, it facilitates exchange of ideas, and frequently offers training in aspects of the field not emphasized at the institution where the bulk of instruction and training has been taken. In time, with the establishment of comprehensive foreign residencies, exchange with residents of other countries does not appear to be impossible.

It appears unlikely that the saturation point of trained anesthesiologists will be reached for a long time. Whereas many other specialties are overcrowded, the reverse is true in anesthesiology. There are few undeveloped locales for its application to the number of trained personnel now available and to be supplied by those returning from the armed forces. This is impressive. Less than 250 anesthesiologists have been certified by the American Board of Anesthesiology. The membership of the American Society of Anesthetists is approximately 1500. On the other hand, over 7500 hospitals are listed by the American Medical Association either as being approved for internships, residencies, and fellowships or as measuring up to the standards set forth by its Council on Medical Education and Hospitals. This shows a ratio of five hospitals to one practicing anesthesiologist. Few specialties are able to show the numerical possibilities of such a ratio for every physician majoring in that field and at the same time to offer the same opportunity for as broad an application of it as does anesthesiology. It is gratifying to think that each hospital would not be capable of supplying

CASE REPORTS

CASE 1. J. M., a 38-year-old Scottish bus driver, was admitted to the hospital in great respiratory distress that was the culmination of 6 years' progressive diminution of exercise tolerance. The respiratory history included four or five episodes of pneumonia, three of these in the first 3 years of life, and frequent milder upper respiratory infections interposed. For 6 years the patient had been coughing up as much as a half cupful of yellowish-white sputum a day. For 4 years his exercise tolerance had been almost nil. There had been episodes of dyspnea at night with cough. He had spent the 4 weeks previous to admission sitting in a chair in more or less continuous respiratory distress.

Physical examination revealed an undernourished, middle-aged orthopneic man breathing with prolonged expiratory and inspiratory effort. The accessory muscles of respiration were extensively called into play, the shoulder girdles being fixed by grasping the bed or arms of the chair with both hands. There was infrequent nonproductive cough and marked cyanosis. The chest was strikingly emphysematous in appearance and hyper-resonant, with diminished tactile fremitus, distant breath sounds, a few scattered crackling rales but no rhonchi. The lower extremities were cold and blue, with soft pitting edema of the feet; circulatory studies established this edema as due to dependency of the legs during the 4 weeks of sitting and not to cardiac disease or cardiac failure. Chest films revealed marked emphysema of the lower lobes of the lung, whereas a review of lipiodol studies made 2 years previously showed bronchial irregularities of the type frequently seen in asthma and chronic bronchitis rather than true bronchiectasis. There was a polycythemia with a hemoglobin of 20 per cent and a red-cell count of 6,300,000; the white-cell count was 12,000, with 73 per cent neutrophils and no eosinophils.

After 9 days' stay in the hospital, during which many forms of medication were exhibited, including ephedrine, aminophyllin and adrenalin, the patient returned home essentially unimproved. One week later he was readmitted in worse respiratory difficulty than before, with cough, productive of thick, yellowish-white sputum, and a low-grade elevation of temperature, both of which rapidly subsided. He was more cyanotic, anxious and apprehensive than previously and was often mentally dull and disoriented. The chest, which showed some medium rales on admission, became completely silent within 48 hours, without change in the characteristics of the respiration. That there was no significant cardiac factor was indicated by a normal ptoic heart, an electrocardiogram within normal limits, a circulation time (Decholin) of 15 seconds (normal) and a venous pressure of 35 mm. of water (low normal). The vital capacity on repeated measurement over a period of days was 1000 cc. The arterial blood taken at a time when the patient's condition was stationary but somewhat improved over what it had been at the time of admission showed an arterial oxygen saturation of only 60 per cent (normal, 95 per cent).

CASE 2. W. D., a 64-year-old ex-salesman, was admitted with the chief complaint of marked shortness of breath on exertion and chronic productive cough, both of 6 years' progression. There was a long history of repeated respiratory infection, beginning with influenza in 1918 and including two episodes of extreme dyspnea of an hour or more in duration, precipitated by walking unusually far and characterized by paroxysmal cough and orthopnea. The admission was precipitated by a "cold" 2 weeks previously, subsequent to which the exercise tolerance was limited to walking 25 yards slowly on the level.

Physical examination showed a pale, undernourished man with somewhat labored respirations and a cyanotic hue of the lips and nail beds. Respiration involved abnormal muscular effort and showed prolongation of the expiratory phase; on deep inspiration the costal margins moved inward. The chest was hyper-resonant, with diminished cardiac dullness and a low diaphragm showing very poor excursion. The breath sounds were faint, with a prolonged expiratory phase and occasional basal rales. A few scattered sibilant inspiratory and expiratory rhonchi were noted on admission, but within 2 or 3 days these adventitious sounds were no longer heard, although there was no marked symptomatic improvement.

X-ray examination showed marked emphysema of the lungs, with a low diaphragm having less than 1 cm. excursion, and a normal ptoic heart. Lipiodol injection of the left lower

main bronchus showed no true bronchiectasis but square endings and minor irregularities in diameter of the bronchioles, "such as is commonly found in asthma and emphysema." A normal electrocardiogram and a circulation time (Decholin) of 16 seconds (normal) supported the x-ray and clinical evidence of cardiac normalcy.

The vital capacity was consistently 1800 cc. The arterial oxygen saturation was 87 per cent (normal, 95 per cent). The carbon dioxide combining power of the plasma was 77 vol. per cent (normal, 50 to 70 vol. per cent). Marked dyspnea resulted from walking slowly 100 feet on the level.

CASE 3. H. H., a 51-year-old shoe cutter, was admitted with the complaint of progressive "shortness of wind" of 10 years' duration. He had been an unusually fine athlete, indulging competitively in running, jumping, boxing, wrestling and various other sports up to the age of 40 years, at which time he was still able to outdistance younger men in 100-yard and 200-yard sprints. During the subsequent 5 to 6 years, he cleaned hen houses on one day a week, with severe choking up from the dust and with cough and mucoid sputum for 2 or 3 days each time. During this period he began for the first time to notice unusual exertional dyspnea, which became progressively more marked, so that at the time of admission he was comfortable at rest but became markedly dyspneic on walking 50 yards at ordinary speed on the level, and after a much shorter distance when the weather was extremely cold. The only respiratory infective history elicited was that of "pneumonia" with hemoptysis after a thoracic injury at the age of 14, morning cough productive of thick yellow sputum for 7 years previous to admission and "influenza" with equivocal hemoptysis 8 months previous to admission.

Physical examination revealed a rather thin, well-developed, relatively young-looking man. The thorax was moderately emphysematous in appearance with an increased anteroposterior diameter, and there was loss of cardiac dullness and a low diaphragm of subnormal excursion. The breath sounds were distant, and there were fine to medium rales in both lung bases but no rhonchi. Chest films revealed marked emphysema, particularly in the lung bases. Lipiodol instilled into the right bronchial tree showed multiple diffuse areas of bronchiectasis in the right base anteriorly, the bronchi near the hilum appearing to be normal. There was a mild polycythemia, with the red-cell count 5,600,000, the hemoglobin 16.6 gm. and the hematocrit 49 per cent; the white-cell count was 7900, with 73 per cent neutrophils, 24 per cent lymphocytes and 3 per cent monocytes. There was no cardiac enlargement. The electrocardiogram showed slight right-axis deviation but was within the limits of normal. The circulation time (Decholin) was 13 seconds (normal).

The vital capacity, to the amazement of many, was consistently 4200 cc. The oxygen saturation of the arterial blood was 89 per cent (normal, 95 per cent).

* * *

It is at once evident that these 3 cases, which have in common extreme restriction in exercise tolerance, vary markedly in history and in various physical factors. J. M. (Case 1), with a vital capacity of 1000 cc. and an arterial oxygen saturation of 60 per cent, was orthopneic, but not extremely so when not excited. W. D. (Case 2), with a vital capacity of only 1800 cc. and an arterial oxygen saturation of 87 per cent, was not much more restricted in activity than was H. H. (Case 3), who had a vital capacity of 4200 cc. and an oxygen saturation of 89 per cent.

VITAL CAPACITY IN EMPHYSEMA

In considering Cases 2 and 3, with vital capacities of 1800 cc. and 4200 cc., respectively, yet similarly restricted exercise tolerance, one might conclude at first glance that the patient in Case 3 must have had a much greater impermeability of the respiratory

stated⁵ that good anesthesia costs more than poor or mediocre anesthesia, but a hospital acquiring the advantages of the modern developments in anesthesia will very soon appreciate that it has been more than repaid for the investment in terms of the patient's satisfaction, mortality and morbidity and the comfort of conscience. It has been estimated that on the average the financial return of the physician anesthetist could be made quite satisfactory by an increase in cost to the patient of only 5 per cent or less of the cost of the *entire* surgical venture, when compared with the cost of similar services by technicians.⁶ Few patients with any degree of intelligence would object to this small increase in expenditure if the benefits to be derived were explained to them, preferably by the surgeon. One effective method of management in this aspect that has come to my notice is for the surgeon to adopt the attitude before the patient that he believes his patients engage him because of his skill, and that it is therefore logical that he engage an anesthetist whose ability in anesthesiology is comparable to his in the field of surgery.

* * *

To summarize, postwar planning in anesthesiology should include first an agency or committee to

accumulate data on positions for trained anesthesiologists and for residencies available to officers requiring additional training when discharged from military duty. A greater number of residencies should be set up now, to begin functioning at the conclusion of the war. The standards of resident training should in no way be lowered. Institutions now without anesthesiologic services should be stimulated to plan for them in order to provide opportunities for those already trained and to be available in the future for those as yet untrained. If the medical profession in general will stimulate externally the natural inherent tendency within the specialty toward expansion, its accomplishment will serve as another example that the practice of medicine is not deserving of the attempted onslaughts on its present structure.

THE ABNORMAL PHYSIOLOGY OF CHRONIC PULMONARY EMPHYSEMA*

Three Contrasting Illustrative Cases

ALFRED F. GOGGIO, M.D.†

BOSTON

IN RECENT years there has been a change in emphasis in the concept of the pathologic physiology of emphysema. To previous ideas concerning the diminution of pulmonary respiratory surfaces due to changes in the alveoli, the loss of capillaries and an increased diffusion coefficient for the blood gases has been added enlightening information about sundry mechanical inefficiencies of pulmonary ventilation. So much excellent work on normal and abnormal respiratory function has been done by Christie,¹⁻⁴ Alexander and Kountz,⁵⁻⁷ Barach,⁸⁻¹⁰ Hurtado,^{11,12} Hermannsen,¹³ Anthony,¹⁴ Knipping,¹⁵ Cournand¹⁶⁻²⁰ and others that it would be impossible to cover the material even in brief in a short space. Furthermore, the present interest in problems of high-altitude aviation has greatly enlarged the appreciation of pulmonocirculatory function and dysfunction and of the usefulness of oxygen in a variety of conditions. It is interesting to realize that in emphysema one has in some degree patients who live at "high altitudes" at sea level.

Clinically the term "pulmonary emphysema" is

*From the Medical Clinic, Peter Bent Brigham Hospital, and the Department of Medicine, Harvard Medical School.

†Formerly, research fellow in medicine, Harvard Medical School

used without sufficient discrimination to include two fairly distinct etiologic types. One of these is the so-called "postural" or "senile" emphysema, which is the more frequent of the two but is relatively seldom of great clinical significance. The more significant type, variously named "chronic hypertrophic" or "obstructive" emphysema, has a somewhat younger age incidence and the etiologic factor of obstruction to breathing is usually fairly prominent on careful inquiry. Christie,⁴ who has done a great deal of valuable work in human emphysema, states that in his experience more than 90 per cent of patients with chronic hypertrophic emphysema give a significant history of asthma and chronic bronchitis. Experimentally, a pathologic lung picture similar to that found in human emphysema of this type has been produced in animals by various methods that produce chronic respiratory obstruction.²¹ It is intended here to present briefly 3 contrasting cases of chronic hypertrophic emphysema that illustrate several illuminating but frequently overlooked aspects of the disease, together with some unusual observations on the physiologic abnormalities that exist.

thus increasing the intrabronchial pressure as the patients do spontaneously, has been pointed out by Barach.⁹ It seems reasonable to suppose, then, that deep breathing exercises should be of use in limbering up the costovertebral articulations, which tend to become fixed, thus making thoracic respiratory movements easier. In Case 1 physiotherapy appeared to be beneficial.

SUMMARY

Three contrasting cases of emphysema are presented that illustrate many features of the disease. The usual method of measuring vital capacity is shown to be misleading owing to its neglect of the thoracic factor. By kymographic vital-capacity recording, the finding of severe limitation of exercise tolerance in the presence of a vital capacity of 4200 cc. is explained.

The importance of the bronchial obstructive element, when present, is stressed. The fact that marked bronchospasm may exist in the absence of adventitious sounds in the chest adds to the importance of the adrenalin test. The value of adrenalin therapy as an inhaled nebula or as adrenalin in solution by injection is emphasized. An objective test of efficiency should be made in each case.

Studies of the arterial blood and alveolar air in these and similar cases are the basis for discussion of the physiologic abnormalities that exist in this disease. These patients to some extent live at "high altitudes" at sea level. The anoxia that is found could be recognized as the cause of many symptoms in severe cases. Oxygen therapy is of value in preventing or breaking the vicious cycle of chronic anoxia, embarrassment of physiologic functions and respiratory fatigue, with resultant increase in general well-being and in exercise tolerance. Discontinuation of oxygen therapy over a long period of time in the same is neither so difficult nor so costly as is generally believed and may be of utmost value.

be both nervous and chemical and may include afferent nervous stimuli from the active muscles, nervous stimuli from the higher centers, an abnormal rise in blood lactic acid and a change in the pH of the blood. Any increase in pulmonary ventilation, due to abnormal mechanical factors, can be accomplished only by great respiratory effort and to a very limited extent. Hence arise the limitation of exercise tolerance and the symptom of dyspnea.

TREATMENT OF EMPHYSEMA

In a disease such as emphysema in which cure is impossible and therapy so limited, the importance of utilizing measures that produce even very minor benefit is obvious. These measures will now be discussed.

Relief of Bronchial Obstructive Factors

That patients with emphysema are not infrequently benefited by bronchodilator drugs has been noted by many observers^{6,10} and has been illustrated in the cases here presented. The introduction of inhalation bronchodilator therapy by Lageder,²⁵ Graeser^{26,27} and others was an important advance in the treatment not only of asthma but also of emphysema. Barach and his co-workers⁸⁻¹⁰ have devised continuous vaporization methods, positive-pressure respiration and other measures of value in the treatment of these diseases. Of the many drugs credited with bronchodilator effect, the most generally effective is probably adrenalin; closely related drugs and ephedrine are also useful.¹⁰ The desirability of any such form of bronchodilator therapy should be objectively tested in each case of emphysema by observing its effect on the maximum voluntary ventilation rate, the vital-capacity exhalation-time curve or the vital capacity (a much less significant measurement).

Oxygen Therapy

The advisability of oxygen therapy in Case 1, in spite of the pronounced anoxemia and marked anoxic symptoms, was questioned by some on the ground that it might prove impossible to discontinue such therapy again in such a severe and chronic illness. Oxygen therapy was instituted in this case discontinuously, using a B.L.B. oronasal mask at flow rates of 3.5 to 4.5 liters a minute in such a way as to ensure more adequate sleep, relief from continual respiratory distress and improvement in general well-being. It was found that a nasal mask that allowed the patient to receive oxygen while eating was valuable in preventing the usual rapid loss of appetite and nausea that otherwise occurred at mealtime. The complete effectiveness of such therapy in returning the arterial oxygen saturation to normal is shown in Table 4. With the combined use of oxygen and adrenalin nebula such improve-

ment occurred in the patient's physical and physiologic condition that at the time of discharge from hospital his arterial oxygen saturation was 85 per cent.

Owing in part to the patient's indiscretions at home, it was soon found that oxygen would have to

TABLE 4. *Effect of Oxygen Therapy on the Oxygen Status of the Blood in Case 1.*

*Done on a different day from the other measurements.

be made available in addition to the adrenalin and supportive medication that had been given. Arrangements were made with a commercial concern to keep the patient supplied with oxygen cylinders. The large cylinders of oxygen were delivered as required and connected for use at a cost of \$3.06 per cylinder; the patient was supplied with an oronasal mask, reducing valve and flow meter at a total cost of \$42 and instructed to use the oxygen sparingly but in such a way as to avoid excessive respiratory fatigue and to ensure adequate sleep at least every other night. He and his wife were thoroughly instructed in oxygen hazards. Follow-up at intervals of six weeks for a period of ten months showed a slowly progressive improvement in the patient's condition. His supplementary oxygen requirements dwindled from two and a half or three cylinders a week to one cylinder in two weeks. Adrenalin continued to be effective. At the time of the last visit the patient seemed to have much more energy than at any time previously. He could go up and down stairs for the first time in more than a year and could walk short distances each day. His color remained good, and his chest clear, and his ankle were free of edema. This therapeutic result was gratifying in view of the extremely grave prognosis at the time of admission to the hospital. This case seemed to illustrate forcibly the fact that in severe chronic pulmonary emphysema, if the vicious circle of respiratory fatigue, chronic anoxia, embarrassment of physiologic functions and general debility is broken, considerable improvement may be expected and maintained.

Abdominal Belts and Other Therapeutic Measures

In milder cases of emphysema and as supplementary measures in the severer cases, efforts to increase the mechanical efficiency of respiration by the use of abdominal belts of various types are reported by some to be attended by considerable success.^{6,28} Our experience with them has not been sufficiently extensive to warrant any definite statement. The value of exhaling between closed lip

overlying shadows and possibly to the minimal amount of calcium present in these small calculi. It has been suggested that an x-ray photograph taken in the oblique position is ideal for delineating calculi, since it eliminates the overlying obscuring shadows.¹

Although in Nicolas's² case the duodenal hemorrhage was due to erosion of a blood vessel by abscess formation, in the present case a calculus mechanically eroded the blood vessel just as it had worked its way through the wall of the duodenum. There have been cases reported in which the calculi have

pancreatic lithiasis there may have been previous subclinical attacks of acute pancreatic necrosis, with resultant calcium deposition, which may serve as a focus or foci of further calcification and resultant formation of calculi.

The history of alcoholism appears to be of significance inasmuch as a review of the literature shows an association of this finding much more frequent than can be explained by pure chance. It is possible that a combination of several factors produces the above condition. Thus, at times stasis with regurgitation of bile due to gastrointestinal upset caused by

FIGURE 2. Photomicrograph of the Pancreas ($\times 35$).

Note the marked fibrosis, the diminution in number of acini, the lymphocytic infiltration and the dilatation of the ducts.

ruptured into the abdominal cavity, and similarly one in which a fistulous tract was formed, extending from the pancreas to the umbilicus, with discharge of pancreatic calculi onto the skin surface.³

Thus, although the mechanism of hemorrhage as a complication seems understandable, the etiology of pancreatic calculi is extremely difficult to explain and has been the subject of numerous theories, none of which have been proved. It has been suggested that the stasis of pancreatic secretion is the causative factor, yet experimentally both pancreatic ducts in animals have been ligated without production of calculi. It has also been claimed that the backflow of bile into the pancreatic ducts may, by its irritative action, lead to calculus formation. Experiments in which bile was introduced into the main pancreatic duct, however, similarly failed to produce the lesion. Pasternack⁴ has suggested that in cases of

alcoholism may initiate a chronic inflammatory reaction in the ducts, and calcium deposition then results, with the formation of calcium phosphate or carbonate stones. This may explain the presence of calcium, for although calcium is not a normal constituent of pancreatic secretion, it may be deposited in chronic inflammation.

In most cases of pancreatic lithiasis the ducts contain stones of varying size. These range from small gravel-like concretions to large stones, one having been reported as weighing 60 gm.⁵ They vary in color from grayish white to yellowish brown, depending on their admixture with organic matter, and their consistence is determined by their calcium content. The walls of the ducts are usually thickened by a fibrotic reaction and are often rigid owing to calcium deposition. The ducts vary in caliber, tending to be dilated, and are tortuous, with oc-

PANCREATIC LITHIASIS WITH ASSOCIATED INTESTINAL HEMORRHAGE*

Report of a Case

HERBERT FANGER, M.D.†

SALEM, MASSACHUSETTS

PANCREATIC lithiasis is not so unusual a clinical and pathologic entity as was originally believed.¹ The complication of fatal intestinal hemorrhage, however, is distinctly infrequent, only 3 cases having been reported in the available literature.^{2,3} Therefore, the following case seems worth while presenting.

CASE REPORT

A. C., a 63-year-old man, had been treated 3 years previous to admission for a "fatty liver" ascribed to alcoholism. He was given a high-caloric diet and high vitamin intake and appeared to recover from this episode. He remained in relatively good health until 1 year before admission, at which time he began to suffer from diffuse, poorly localized abdominal pain that was intermittent. No radiation of this pain was noted, nor was there any back pain. During that period, there were alternating bouts of constipation and diarrhea of increasing severity. In the 6 months before hospitalization, the patient noted occasional tarry or blood-streaked stools. His appetite diminished and he experienced easy fatigability. There was a 20-pound weight loss in 1 year. Two days before entry he had a severe attack of diarrhea, the stools being bright red. On entry he was quite weak and dyspneic on exertion.

Physical examination was not remarkable. The outstanding finding was marked pallor of the skin. Examination of the abdomen was negative.

Throughout the hospitalization, the patient had multiple episodes of bleeding into the bowel, as evidenced by tarry stools and at times by bright-red fluid blood. The bleeding time, coagulation time, clot-retraction time, prothrombin time and platelet counts were within normal limits. A brom-sulfalein function test of the liver was normal. Repeated barium enemas as well as x-ray examination of the gastrointestinal tract were not considered to be diagnostic. Sigmoidoscopy revealed fluid blood trickling down into sight, but no masses or other specific lesions could be made out.

Whereas usually the stools were positive for bile, for a period of 5 days there were clay-colored stools with no bile demonstrable. Urine examinations were at all times negative, no sugar being present.

In spite of repeated transfusions, the patient was considered a poor operative risk, and expired before a planned exploratory laparotomy could be performed.

Autopsy. The autopsy was limited to the abdomen. The major pathology was found in the second part of the duodenum. Just medial to the ampulla of Vater and at a slightly higher level there was an ulceration of the mucosa 4 mm. in diameter, from which protruded a fresh, friable blood clot. On its removal there was seen at the base of the ulceration a brownish-white, mulberry-shaped stone 3 mm. in diameter impinging on a small eroded blood vessel, the apparent source of hemorrhage (Fig. 1). On careful dissection, the ulceration was seen to represent the orifice of a sinus tract that, when traced into the pancreas, terminated in the duct formed by the union of the two major pancreatic ducts. This sinus tract was apparently formed by the inflammatory reaction evoked by the pancreatic calculi, which had caused erosion of the duodenal wall. Throughout the length of the pancreatic ducts there were numerous grayish-white, friable, granular calculi varying in size from tiny particles to masses 3 mm. in diameter. The ducts were markedly dilated, there being a cystlike dilatation just proximal to the ulceration through the duodenal wall. The margins of the dilated ducts were roughened and there was a definite fibrosis of the walls. The surrounding parenchyma showed a diffuse fibrosis with

many small foci of calcification, possibly representing gravel in the small ducts.

The common bile duct was distended in its distal third but no obstruction was demonstrable. The gall bladder was of normal size and free of calculi. The liver was enlarged and tawny yellow, and on section presented a slightly yellow

FIGURE 1. Photograph of the Ulceration in the Duodenum with the Pancreatic Calculus at Its Base (x2).

The probe is in the ampulla of Vater.

surface. The remainder of the abdominal examination was not remarkable except for the presence of blood in the stomach and intestines.

The significant findings on microscopic examination were confined to the pancreas and liver. The pancreas revealed dilated ducts containing cellular debris. There was a marked interlobular and intralobular fibrosis, with infiltration by lymphocytes and macrophages and a reduction in the number of acini. The islets of Langerhans were uninvolved (Fig. 2). The liver showed marked fatty infiltration of the hepatic parenchyma.

The pathologic diagnoses were as follows: pancreatic lithiasis, with false-passage formation and ulceration through the duodenal mucosa and exsanguination from a bleeding vessel at the base of the ulcer, and fatty infiltration of the liver.

The intestinal hemorrhage markedly masked the symptomatology, making a clinical diagnosis impossible. Ideally, the radio-opaque calculi are demonstrable on x-ray examination of the abdomen. In this case, the calculi were not observed owing to

MEDICAL PROGRESS

THE TREATMENT OF GOUT*

WALTER BAUER, M.D.,† AND FRIEDRICH KLEMPERER, M.D.‡

BOSTON

IN A previous article¹ of this series gout was defined as a hereditary constitutional disease, preeminently of males, occurring at any age and in most cases characterized by recurrent attacks of acute arthritis, caused by deposits of sodium urate crystals. Gout may be manifested only by an asymptomatic hyperuricemia²⁻⁴ that, throughout the life of the patient, may remain the only sign of the disease. Such asymptomatic hyperuricemia, although rarely demonstrated, probably always antedates the first attack of arthritis. Once the hyperuricemia is established it persists throughout life regardless of the incidence or degree of joint involvement. Treatment of gout, in order to be specific, should therefore be based on the knowledge not only of the cause of hyperuricemia but also of the factors that, once hyperuricemia is established, lead to the precipitation of urates in articular and other tissues.

The factors that lead to hyperuricemia in gout have not been fully explained. Theoretically, the elevation in the blood uric acid level may be the result of decreased destruction, increased formation or decreased elimination of uric acid. Since, however, evidence is entirely lacking that uricolysis ever occurs in human beings, the hyperuricemia cannot be ascribed to the first-named mechanism. If it were due to enhanced uric acid formation, a relatively greater excretion would be demonstrable in all patients, as is the case with glucose in diabetes. If, on the other hand, the hyperuricemia were the result of impaired renal function, the uric acid excretion would be decreased, a finding actually observed by many workers. Most gouty subjects when kept on a low-purine diet excrete less than 500 mg. a day, the average being lower than that found in normal persons.^{5, 6} A few cases of increased uric acid excretion are on record,^{5, 7} however, and have led certain workers to postulate that an augmented production of uric acid is responsible for the hyperuricemia of gout.⁷ Although no explanation can be given for these rare cases, it seems reasonable to accept the mass of evidence showing that the daily uric acid excretion of gouty subjects is not increased. It therefore appears that the intermediary purine

metabolism of the gouty patient is normal and that his hyperuricemia is accounted for by a limitation of renal excretion of uric acid that is the end product of purine metabolism.

Hyperuricemia, although an essential feature of gout, cannot be regarded as the sole cause of urate deposition in tissues and arthritis in gout. This is apparent from the following well-established observations. First, hyperuricemia as a result of renal disease or increased formation of uric acid, such as occurs in leukemia and other conditions that lead to an increased breakdown of nuclear tissue, does not cause gouty arthritis except possibly in patients who already have gout as evidenced by the history of preceding attacks or a positive family history. Second, the serum urate concentration does not reflect the severity of the gouty arthritis. It is well known that a patient may have extreme hyperuricemia although clinically the disease is mild; conversely, in some patients with severe disease the serum uric acid concentration hardly exceeds the normal value. In a given patient with gout there is no correlation between clinical symptoms and the fluctuations in urate concentration in the serum. Occasionally patients are seen who have their severest attacks at times when the urate concentration is at its lowest, whereas they may remain asymptomatic at periods when it is high.

The fact that an elevation of urate concentration alone does not necessarily cause precipitation is explained by the strong tendency of sodium urate to remain in supersaturated solution. According to the best available data,⁸ a serum with normal sodium and hydrogen-ion concentrations is supersaturated if the urate concentration exceeds 6.5 mg. per 100 cc. This level must be regarded as an approximation of the true solubility and may have to be revised in the future. Precipitation of sodium urate is a physical impossibility unless the body fluids are supersaturated. Clinical experience that gouty attacks occur only in patients whose serum uric acid concentration is elevated⁸ indicates that the solubility figure given above is approximately correct.

It appears likely, therefore, that the serum of gouty patients is supersaturated in regard to sodium urate. The physicochemical factors that initiate precipitation under these conditions are entirely

*This is publication No. 80 of the Robert W. Lovett Memorial Foundation for the Study of Crippling Disease, Harvard Medical School.

§It should be remembered that even the best methods^{9, 10} for the determination of uric acid are subject to a variety of errors that can be eliminated only by meticulous care and frequent checks. Determinations on whole blood yield lower values than do those on serum. It is possible that the rare exceptions to the above statement are explained by inadequacies of the method.

casional areas of cystic sacculations corresponding to the location of the larger calculi.

The pancreatic parenchyma shows initially an interlobular fibrosis, subsequently developing into an interstitial fibrosis, with consequent replacement of the acini. Only in the later stages does a fibrotic replacement of the islets of Langerhans occur. Therefore, although diabetes mellitus is frequently associated with pancreatic lithiasis, it is not invariably found and, when present, occurs in the latter stages of the disease.

Snell and Comfort¹ in an excellent review of the subject have discussed the physiopathology and symptomatology in a highly enlightening fashion.

As a result of the extensive pancreatic fibrosis and consequent reduction in acini, there is a marked diminution in secretion of the various pancreatic enzymes. The lack of the fatty enzymes, steapsin and lipase, produces the steatorrhea that is so frequently seen. In the case presented above, the fatty nature of the diarrhea was undoubtedly obscured by the intestinal bleeding.

Owing to inadequate elaboration by the pancreas of lipocaic, the hormone functioning in the regulation of the proper deposition of fat in the liver parenchyma, this organ undergoes fatty infiltration and consequent enlargement. The hepatotoxic effect associated with alcoholism is an additional factor.

Abdominal pain is a frequent and a most prominent complaint. This pain is probably due to overdistention of the pancreatic ducts or to temporary spasm of the ampulla of Vater, with obstruction to biliary flow. In addition, there are profound reflex disturbances in the motor and secretory functions of the digestive tract, with consequent production of pain. The pain, however, is distinctly variable in type and location. It is usually intermittent, varying from severe colic to mild, evanescent abdominal distress. It may be confused with biliary colic, but more often it tends to a left-sided extension and may be further projected to the back to the left costovertebral angle and up between the shoulder blades. At times, the pain is excruciating

and associated with nausea and vomiting. Thus, although pain is usually associated with pancreatic lithiasis, it by itself is not of great diagnostic aid owing to its great variability. In this case, the dull, diffuse, nonlocalizing abdominal pain, although in retrospect consistent with pancreatic lithiasis, was by itself in no way diagnostic.

By far the best diagnostic aid is x-ray examination. The finding of radio-opaque shadows along the axis of the pancreas extending to the left of the vertebral column is almost pathognomonic. To be sure, one must differentiate the shadows from those due to gallstones and renal calculi. At times, the calculi are not sufficiently opaque owing to a low calcium content, and in such cases the overlying loops of bowel may obscure the outline of these shadows.

In the absence of positive x-ray findings, the diagnosis of pancreatic lithiasis is a difficult one, because the symptomatology is so variable. The finding of some of the cardinal symptoms—abdominal pain, steatorrhea, hepatomegaly of unexplained etiology and occasionally diabetes mellitus—should, however, make one suspect this disorder and lead to investigation and possible confirmation.

SUMMARY

A case of pancreatic lithiasis with sinus-tract formation and fatal intestinal hemorrhage due to erosion of a blood vessel is presented. The theories of pancreatic calculus formation and symptomatology are discussed. The importance of x-ray examination as a diagnostic aid is emphasized.

Correction. In the article "Treatment of Meningococcic Meningitis with Penicillin" by Drs. Manson Meads, H. William Harris, Bernardo A. Samper and Maxwell Finland, which appeared in the October 12 issue of the *Journal*, the second and third sentences in the section "Tests for Sensitivity of Strains" on page 512 should be changed to read as follows: "One strain was completely inhibited by 0.36 units per cubic centimeter, 3 by 0.18 units, and 1 by 0.09 units. The first was obtained from Case 7; the organism obtained after eleven days of penicillin therapy in the same case was also tested and showed an increase in resistance, 0.71 units per cubic centimeter being required to inhibit completely its growth."

thing and lessens the chance of accidental jolting. At compresses every three hours are a useful adjunct, although an occasional patient derives greater relief from cold packs. Moist heat is always preferable to dry heat. Diathermy as a rule is not tolerated well.

INTERVAL TREATMENT

Ideally, the treatment of gouty subjects between acute attacks should be aimed at the prevention of the attacks and of complications. In accordance with a widely disseminated belief that adherence to a rigorous purine-free diet reduces or eliminates acute seizures and sufficiently alters the course of the disease to prevent chronic arthritis and the complications of gout, countless gouty patients have been subjected to undue and sometimes serious nutritional restrictions. Although it is well established that such a regimen slightly reduces the serum uric acid level, a careful survey of the past and current literature reveals the astonishing fact that conclusive evidence pertaining to the effect of dietary restriction of purine intake on clinical gout is entirely lacking. Talbott¹² observed no effect on the frequency or severity of the acute attacks in a group of patients maintained on a carefully measured low-purine diet. Likewise, we have seen no therapeutic effect from a low-purine diet or any increase in symptoms when patients who had followed such a rigorous regimen returned to a normal, well-balanced diet.

The conspicuous failure of the low-purine diet to control the recurrence of acute attacks of gout has in no way diminished the search for a dietary means of control of the disease. Extensive trials of a diet almost entirely devoid of fat have been conducted. This mode of treatment was initiated because of the following observations. In 1924, Lennox,¹³ found a significant increase of serum urate concentration in starving subjects whose caloric requirements were met by their own adipose tissue. Harding et al.¹⁴ were able to reproduce these changes by feeding excessive amounts of fat to healthy persons. Subsequently Lockie and Hubbard¹⁵ apparently precipitated attacks in gouty patients by excessive feeding of fat and therefore advocated a diet low in fat as a preventive measure. A strictly fat-free diet forms part of the regimen that has been advocated recently by Bartels.¹⁶ At the present time there is no agreement about the value of this diet. According to our experience gouty attacks cannot be precipitated with any regularity by a high-fat intake, nor is the amount of fat contained in a well-balanced diet sufficient to cause significant retention of uric acid.¹⁷ Furthermore, in our experience the omission of fat from the diet has not proved beneficial.

Unqualified abstinence from alcoholic beverages is almost uniformly advocated, and some clinicians consider the ingestion of alcohol the most impor-

tant of all precipitating factors. We have not, however, been able to provoke attacks experimentally by administration of large quantities of liquor. Despite complete abstinence, a large number of patients continue to suffer from repeated gouty attacks. In a previous article we¹ have quoted specific cases that serve to emphasize that the instrumentality of alcohol in precipitating gouty arthritis is unproved.

In outlining a regimen for gouty patients we are guided by the following considerations. The diet should be balanced and should contain adequate amounts of protein, iron and vitamins. Since circulatory complications are frequent in gout, obesity should by all means be avoided. Drastic curtailment of purine intake is inadvisable because it can be accomplished only by a diet composed of a small variety of vegetables and cereals, eggs and dairy products. Such a diet is not only highly monotonous and unpalatable but, if followed for a prolonged period, is likely to lead to serious deficiency states. Few patients are willing to adhere strictly to such a regimen. Moreover, a reasonably low purine intake can easily be accomplished if only the few foods that are listed in Table 1 are omitted from the diet. This restriction offers no hardship to the patient, but there is no pertinent evidence that the

TABLE 1. Purine Content of Certain Foods.

Food	PURINE CONTENT mg./100 gm.
Sweetbreads	825
Anchovies	360
Sardines	300
Liver	230
Kidneys	200
Brains	195
Meat extracts	150

number and severity of acute seizures is thereby reduced. However, since in most cases of gout the elimination of uric acid is diminished, it appears unreasonable to introduce unnecessary amounts of purines. It is possible that the omission of the few foods mentioned retards the growth of tophi, which occasionally in the late stages of the disease form the chief cause of the patient's disability.

Cinchophen has been extensively employed in the interval treatment of gouty arthritis. Its use is advocated in doses of 0.5 gm. three times daily. As precautionary measures against toxic effects a daily fluid intake of 2000 cc., a high-carbohydrate diet and maintenance of an alkaline urine are usually recommended. There is no doubt that cinchophen does cause a temporary increase in urate excretion and so lowers the blood urate level, but because of its toxicity, and since precisely the same results can be achieved without fear of complications by the use of salicylates, we believe that cinchophen should never be employed in the treatment of gout.

Salicylate is the only safe drug known that causes efficient elimination of urates. In the past acetyl-

unknown. The fact, however, that in supersaturated solutions the formation of precipitate is largely independent of the concentration explains the lack of correlation between the serum uric acid level and the incidence of attacks in gout. Whether attacks are possible if the urate concentration of the body fluids falls below the level of 6.5 mg. cannot be decided so long as the magnitude of the true solubility remains uncertain.

It is therefore evident that serum uric acid determination cannot be used as a measure of the therapeutic efficacy of any regimen and that treatment can be evaluated only on a clinical basis. An important reason for the disagreement about the value of various therapeutic measures lies in the extreme variability of the clinical course of gout. It is well known that patients who have been bedridden for months because of rapidly recurring attacks of great severity often, without any known cause, go into periods of complete freedom from joint pain that in some cases last for years. On the other hand, patients are not infrequently seen who, after having had only rare attacks, spontaneously and without any change in regimen lapse into a state of chronic, crippling disease. The nature of the gouty attack is equally unpredictable. Although typically accompanied by extreme pain and all signs of acute inflammation of the involved joint, it may be evidenced only by pain lasting for a short time without any objective signs. The pain and swelling may subside suddenly during the first day or may last for days or weeks, or the attack may even lead to chronic deformity of a joint. Since it is impossible to account for the variations in the natural course of the disease, it is obvious that evaluation of any treatment, whether directed toward prevention of attacks or toward alleviation of the acute symptoms, is extremely difficult. It is owing to this difficulty that in the past many different and contradictory methods of treatment have been proposed.

TREATMENT OF ACUTE ATTACK

The treatment of the acute attacks of gouty arthritis is satisfactory. Colchicum, obtained from the seeds of *Colchicum autumnale* (fall crocus), was first recommended by Alexander of Tralles (525-605) and, as colchicine, remains the drug of choice. Its mode of action in gout is unknown beyond the fact that it does not affect the hyperuricemia or the renal excretion of uric acid. We have seldom seen it fail to bring relief when given properly during the first few hours of an acute attack. When administration is delayed, the effect is less certain, but an attempt to shorten an attack by administration of colchicine is advisable at any stage of the disease. It has fallen into disrepute in times past, undoubtedly owing to the use of impure or impotent preparations in the form of wine or tincture. Therapeutic failures can often be avoided if the drug is always administered as crystalline colchicine. The

preliminary use of a saline cathartic is recommended by some.¹¹

We prescribe 0.5 mg. every hour or 1 mg. every two hours, until relief from pain is obtained or until diarrhea or nausea and vomiting result, when the drug is discontinued. Provided the patient is kept at bed rest, pain and swelling usually subside within twenty-four to seventy-two hours after the first loose bowel movement. Rarely do the articular symptoms disappear sooner. The ensuing diarrhea is frequently severe enough to require treatment with paregoric; 4 cc. is given following each loose stool until the diarrhea is checked. Bismuth subcarbonate may be used instead of or in conjunction with the paregoric. Once the amount of colchicine necessary to produce such symptoms has been established in a patient, the total dose may be reduced by one or two tablets (0.5 or 1.0 mg.) to avoid severe gastrointestinal symptoms without curtailing the desired effect. The total amount required to alleviate the acute attack varies from 4 to 8 mg. of colchicine and rarely exceeds this quantity.

We have never observed any other untoward effects from crystalline colchicine. Hypersensitivity to the drug is unknown, nor does it lose its efficacy with repeated administrations. The patient should always carry colchicine. The appearance of any prodromal symptoms or the first twinges of articular pain call for immediate institution of therapy. If these rules are followed, the patient will be spared many prolonged and incapacitating seizures. Some workers unwisely object to the side action of colchicine and delay therapy until the attack has fully developed.

We can find no indications for the use of cinchophen and substances closely related to it, either alone or in conjunction with colchicine. To be sure, the risk attendant on their administration—primarily that of acute liver necrosis—is statistically small, but minor symptoms of toxicity are a more frequent annoyance to the patient and serve as warning signals for immediate cessation of therapy. In omitting these drugs, we are guided by the fact that colchicine, when given properly, is not only entirely safe but also much more effective. Morphine or codeine may be needed to ensure comfort before the colchicine effect is secured. At the time of the seizure, no dietary measures other than those given for any painful illness of short duration are required. Patients rarely desire anything more than liquids and soft foods, and a daily fluid intake of 3000 to 4000 cc. should be encouraged.

Absolute bed rest is always indicated for the duration of the attack, whether or not weight-bearing joints are involved. Premature resumption of normal activity not infrequently precipitates an exacerbation. Avoidance of even normal joint use prevents minor trauma, thereby shortening the period of incapacitation. Protection of the affected part by a cradle eliminates the pressure from bed-

thing and lessens the chance of accidental jolting. Hot compresses every three hours are a useful adjunct, although an occasional patient derives greater relief from cold packs. Moist heat is always preferable to dry heat. Diathermy as a rule is not tolerated well.

INTERVAL TREATMENT

Ideally, the treatment of gouty subjects between acute attacks should be aimed at the prevention of the attacks and of complications. In accordance with a widely disseminated belief that adherence to a rigorous purine-free diet reduces or eliminates acute seizures and sufficiently alters the course of the disease to prevent chronic arthritis and the complications of gout, countless gouty patients have been subjected to undue and sometimes serious nutritional restrictions. Although it is well established that such a regimen slightly reduces the serum uric acid level, a careful survey of the past and current literature reveals the astonishing fact that conclusive evidence pertaining to the effect of dietary restriction of purine intake on clinical gout is entirely lacking. Talbott¹² observed no effect on the frequency or severity of the acute attacks in a group of patients maintained on a carefully measured low-purine diet. Likewise, we have seen no therapeutic effect from a low-purine diet or any increase in symptoms when patients who had followed such a rigorous regimen returned to a normal, well-balanced diet.

The conspicuous failure of the low-purine diet to control the recurrence of acute attacks of gout has in no way diminished the search for a dietary means of control of the disease. Extensive trials of a diet almost entirely devoid of fat have been conducted. This mode of treatment was initiated because of the following observations. In 1924, Lennox,¹³ found a significant increase of serum urate concentration in starving subjects whose caloric requirements were met by their own adipose tissue. Harding et al.¹⁴ were able to reproduce these changes by feeding excessive amounts of fat to healthy persons. Subsequently Lockie and Hubbard¹⁵ apparently precipitated attacks in gouty patients by excessive feeding of fat and therefore advocated a diet low in fat as a preventive measure. A strictly fat-free diet forms part of the regimen that has been advocated recently by Bartels.¹⁶ At the present time there is no agreement about the value of this diet. According to our experience gouty attacks cannot be precipitated with any regularity by a high-fat intake, nor is the amount of fat contained in a well-balanced diet sufficient to cause significant retention of uric acid.¹⁷ Furthermore, in our experience the omission of fat from the diet has not proved beneficial.

Unqualified abstinence from alcoholic beverages is almost uniformly advocated, and some clinicians consider the ingestion of alcohol the most impor-

tant of all precipitating factors. We have not, however, been able to provoke attacks experimentally by administration of large quantities of liquor. Despite complete abstinence, a large number of patients continue to suffer from repeated gouty attacks. In a previous article we¹ have quoted specific cases that serve to emphasize that the instrumentality of alcohol in precipitating gouty arthritis is unproved.

In outlining a regimen for gouty patients we are guided by the following considerations. The diet should be balanced and should contain adequate amounts of protein, iron and vitamins. Since circulatory complications are frequent in gout, obesity should by all means be avoided. Drastic curtailment of purine intake is inadvisable because it can be accomplished only by a diet composed of a small variety of vegetables and cereals, eggs and dairy products. Such a diet is not only highly monotonous and unpalatable but, if followed for a prolonged period, is likely to lead to serious deficiency states. Few patients are willing to adhere strictly to such a regimen. Moreover, a reasonably low purine intake can easily be accomplished if only the few foods that are listed in Table 1 are omitted from the diet. This restriction offers no hardship to the patient, but there is no pertinent evidence that the

TABLE 1. *Purine Content of Certain Foods.*

Food	PURINE CONTENT mg/100 gm.
Sweetbreads	825
Anchovies	360
Sardines	300
Liver	230
Kidneys	200
Brains	195
Meat extracts	150

number and severity of acute seizures is thereby reduced. However, since in most cases of gout the elimination of uric acid is diminished, it appears unreasonable to introduce unnecessary amounts of purines. It is possible that the omission of the few foods mentioned retards the growth of tophi, which occasionally in the late stages of the disease form the chief cause of the patient's disability.

Cinchophen has been extensively employed in the interval treatment of gouty arthritis. Its use is advocated in doses of 0.5 gm. three times daily. As precautionary measures against toxic effects a daily fluid intake of 2000 cc., a high-carbohydrate diet and maintenance of an alkaline urine are usually recommended. There is no doubt that cinchophen does cause a temporary increase in urate excretion and so lowers the blood urate level, but because of its toxicity, and since precisely the same results can be achieved without fear of complications by the use of salicylates, we believe that cinchophen should never be employed in the treatment of gout.

Salicylate is the only safe drug known that causes efficient elimination of urates. In the past acetyl-

salicylic acid (aspirin) has been recommended in doses of 5 to 6 gm. on three consecutive days of each week.¹⁸ Figure 1 demonstrates the changes in the serum level and excretion of uric acid that take place on this regimen. During the seven days

FIGURE 1. The Effect of Intermittent Acetylsalicylic Acid Medication on the Serum Uric Acid Level and the Uric Acid Excretion.

preceding administration of salicylates the average daily uric acid excretion amounted to 466 mg. During the twenty-four-day period of intermittent administration of salicylates the average was 433 mg. It is apparent that, although marked urate diuresis was caused by the administration of acetylsalicylic acid, a corresponding amount of urate was retained during the immediately ensuing period, with the result that the total amount of urate excreted was not significantly altered by this regimen. The serum urate level likewise underwent fluctuations and reached high levels on the days when no salicylate was given. After a few months of such treatment tolerance is developed and the serum uric acid becomes stabilized at its usual level.

Salicylates are effective in promoting the excretion of uric acid only when given in large amounts. They are ineffective in doses of less than 4 gm. a day, and we¹⁹ have seen actual retention of uric acid with marked increase in the serum concentration when doses of 1 to 2 gm. were given. Striking reduction of the serum urate concentration is observed when salicylates are given in continuous daily doses of 5 to 6 gm. Under these conditions a lowering of the blood urate level to one third its

original level is frequently observed. Figure 2 illustrates the typical changes that occurred in a patient treated with continuous daily doses of 5 gm. of acetylsalicylic acid. It is evident, however, that the reduction of the serum urate concentration is temporary, and a gradual return to the original level usually occurs within about three months.

Clinical observation has proved that it is impossible to prevent attacks of gouty arthritis by continuous administration of salicylates. This is not surprising in view of the fact that it is impossible to maintain the serum uric acid permanently below the critical level of about 6.5 mg. Therefore, we advise neither continuous nor intermittent administration as a routine procedure. On the other hand, in a number of patients studied while in a state of rapidly recurring attacks we have not observed the recurrence of new joint symptoms during the first few weeks of treatment with massive doses of acetylsalicylic acid. Only more extensive studies will enable us to decide whether in these patients the cessation of attacks was caused by the administration of salicylates or whether we were dealing with the natural remissions that occur so frequently in the course of gouty arthritis. These studies, although inconclusive as to the therapeutic value of salicylates, demonstrate clearly that, without any inherent risk, results can be obtained by their use that equal those ascribed to cinchophen. Gastrointestinal symptoms, occasionally encountered after

FIGURE 2. The Effect of Continuous Acetylsalicylic Acid Medication on the Serum Uric Acid Concentration. The shaded area represents the administration of 5 gm. acetylsalicylic acid daily. The black area signifies the incidence of attacks of gouty arthritis.

large doses of acetylsalicylic acid, can easily be controlled by the administration of equal amounts of sodium bicarbonate. There is no justification for

giving large doses of salicylates continuously except in patients who have lapsed into a state of rapidly recurring attacks of gouty arthritis.

Some authors^{20, 21} advise the giving of 10 gm. of glycine daily for three days of each week in conjunction with salicylates as another means of augmenting the output of urates. We have never employed this combination, but our experience with glycine alone has been disappointing. We have seen no beneficial effects from the administration of thiamine chloride. The administration of small daily doses of colchicine (1 mg.) in the interval, as suggested by some,¹² although harmless, has had no preventive value.

The injection of purified uricase, prepared from pig's liver, has recently been attempted by Oppenheimer and Kunkel.²² These authors were unable to demonstrate any action of the injected enzyme on the uric acid concentration in the blood of men.

Chronic gouty arthritis is least amenable to treatment of any form of the disease. In this stage, acute attacks are relatively infrequent and mild. The patient's disability and pain are due primarily to the permanent joint changes that have been caused by the preceding acute attacks. Some of our patients feel certain that the giving of 0.5 mg. of colchicine three times a day provides a measure of relief. Regular rations of salicylates are often necessary for the control of pain. Active or passive exercise should be prescribed whenever possible to prevent increasing limitation of the involved joints, but severe pain may make immobilization of a joint imperative. In selected cases, operative correction of joint deformities has yielded fair results. Application of foot pads or special shoes may be indicated. Troublesome tophi can usually be excised without precipitating an attack of gout.²³ We know of no special benefit derived from spa therapy.

The cardiovascular disease and vascular nephritis that so frequently complicate gout are not preventable and must be treated according to the specific needs of the patient. The unexplained high incidence of urinary calculi in gouty subjects, amounting to 12 per cent in Hench's²⁴ series, can probably be reduced if a liberal daily fluid intake (3000 cc.) is encouraged in all patients. Alkalinization of the urine by the daily administration of 8 to 16 gm. of sodium citrate is advised in those patients who are known to have formed uric acid stones. It is not recommended as a routine procedure because calcium phosphate stones are known to have occurred in association with gout.¹⁷

SUMMARY

Gout, which is a hereditary disorder, cannot be prevented or cured. Interval treatment with diet, drugs or a combination of both as advocated to date has been disappointing. After a careful survey of personal results and a review of the literature, it is concluded that there is no pertinent evidence that these measures alter the clinical course of the disease or even lessen the incidence of attacks. The treatment of the acute attack is highly satisfactory, colchicine being the drug of choice.

CASE 30461

PRESENTATION OF CASE

First admission. A sixty-seven-year-old cook entered the hospital because of abdominal swelling.

The patient was essentially well until one year before entry, when he developed orthopnea, exertional and nocturnal dyspnea, which had increased in severity, especially during the month before entry. Three or four weeks before entry he developed a cough productive of a small amount of white sputum. Six days prior to admission, swelling of the abdomen and ankles appeared and progressed to the point where he was unable to work.

The past history was essentially negative except for the imbibition of two or three glassfuls of beer and occasional drinks of whisky daily for twenty years and, before that, two or three pints of beer and about a gallon of wine daily for some years.

Physical examination showed an obese, slightly cyanotic, orthopneic and dyspneic man. The anteroposterior diameter of the chest was increased, and its expansion limited. Breath sounds were diminished toward both bases, more so on the right, with a few crackling and moist rales. Loud wheezes and rhonchi were heard throughout the chest on inspiration and to a less degree on expiration, persisting after cough. The heart was moderately enlarged, with the apex 4 cm. beyond the mid-clavicular line. The rate was regular. There was no pulse deficit. A loud, grating "meat slicer" murmur was heard over the precordium, loudest over the aortic area, and was transmitted to the neck vessels. No diastolic murmurs were audible. The aortic second sound was greater than the pulmonic. The abdomen was distended, with a fluid wave and shifting dullness. The edge of the liver extended 10 cm. below the costal margin and was slightly tender. There was moderate scrotal edema. The prostate was diffusely enlarged and firm. There was slight pitting edema of the legs.

The blood pressure was 135 systolic, 75 diastolic. The temperature was 100°F., the pulse 80, and the respirations 25.

*On leave of absence.

Examination of the blood showed a red-cell count of 5,540,000, with 95 per cent hemoglobin, and a white-cell count of 7250, with 61 per cent neutrophils. The urine gave a + test for albumin and, after the first day, a green or olive reaction with Benedict's reagent. A blood Hinton test was negative. An electrocardiogram revealed auricular flutter, with four-to-one block, the ventricular rate being 75, and the auricular 300. The axis was normal, T₁ inverted, T₂ and T₃ upright, and T₄ low but upright. An x-ray film showed marked enlargement of the heart in the region of the left ventricle. The right border was also prominent. The transverse diameter was 17.2 cm., and the internal diameter 32.2 cm. In the left oblique view an area of calcification was seen in the region of the aortic valve. The hilar shadows were prominent, but the vascular markings were only slightly increased. There was no fluid in the pleural cavities. A plain film of the abdomen showed moderate enlargement of the liver. The lower border extended about 8 cm. below the costal margin laterally.

The patient was given 0.3 gm. (4½ gr.) of digitalis daily for six days, — thereafter, 0.1 gm. daily, — 1 gm. of ammonium chloride three times a day and occasional intravenous injections of Mercupurin. The fluid intake was limited to 1500 cc. He failed to show any spectacular diuresis at first, but the edema gradually decreased. The orthopnea and dyspnea became much less. On the eleventh hospital day, the fasting blood sugar was 210 mg. per 100 cc., the nonprotein nitrogen 32.5 mg., and the protein 7.7 gm., with an albumin-globulin ratio of 1.4. A cephalin-flocculation test was +++ in twenty-four hours and ++++ in forty-eight hours. A bromsulfalein test gave 70 per cent retention.

A urine examination on the day of discovery of high blood-sugar level revealed an orange reaction for sugar and a ++ test for acetone. He was given a high carbohydrate diet, and the diabetes was controlled with insulin. An electrocardiogram on the twelfth hospital day revealed conversion of the auricular tachycardia to fibrillation. The patient improved for a few days, but with increased fluid intake the output decreased and there was recurrence of the edema, which was then treated by limitation of the fluid intake and diuretics. On the thirtieth hospital day, however, he had ascites and moderate pitting edema of the ankles. The liver edge was felt 8 cm. below the costal margin. The heart rate was slow (40) but regular.

He improved some in the next six days and was discharged home on 0.1 gm. of digitalis daily, 1 gm. of ammonium chloride three times a day, a high-vitamin diet and provision for the control of the diabetes.

Final admission (two months later). After discharge the patient was followed in the Out Patient Department, where he was given occasional intra-

ous injections of Mercupurin. On one occasion, 3500 cc. of deep-straw-colored ascitic fluid, with a specific gravity of 1.018, was withdrawn, with marked relief. During the first month the heart rate was 60, with frequent bigeminy. Although the patient claimed that he followed the regimen prescribed for him, the fluid reaccumulated and he became increasingly dyspneic and orthopneic and extremely weak and tired. He was admitted to the hospital.

Physical examination showed marked edema of the legs, moderate respiratory distress, but no cyanosis. The neck veins were distended. The mucous membranes and tip of the tongue were smooth. Breath sounds were depressed over both bases, more so on the right, with absent tactile fremitus and evidence of fullness. The heart was regular but slow. All the sounds were distant and of poor quality. There was a Grade III systolic murmur, which masked the first sound over the entire precordium. The abdomen was markedly distended. The liver edge was ballotable six fingerbreadths below the costal margin. The spleen was enlarged but not palpable. The lower extremities showed moderate pitting edema, which gradually diminished to slight swelling of the umbilical region.

The blood pressure was 140 systolic, 70 diastolic. The temperature was 99.4°F., the pulse 40, and the respirations 22.

Examination of the blood showed a red-cell count of 3,900,000, with 12.5 gm. of hemoglobin, and a white-cell count of 10,050, with 69 per cent neutrophils. The urine gave a ++ test for albumin and was negative for sugar. The stools were guaiac negative. The venous pressure was 16 mm. An electrocardiogram showed auricular fibrillation, with a rate of 55. The axis was normal. There were a few premature ventricular beats. T₁ was flat or slightly inverted, ST₂ depressed, T₂ low, and T₃ and T₄ flat. The fasting blood sugar was 102 mg. per 100 cc., the nonprotein nitrogen 22.5 mg., and the protein 7.5 gm. An x-ray film of the chest showed a large amount of fluid in the right pleural cavity, extending to the level of the eighth rib in the midaxillary line. Some increase in the vascular markings was apparent throughout both lungs. The left costophrenic angle was hazy.

The patient was kept on essentially the same program of therapy as previously. On the third day he had a profuse epistaxis, which stopped spontaneously. On the fifth day, 3000 cc. of straw-colored fluid was withdrawn from the abdomen. There was temporary improvement, but his condition became progressively worse and he died on the eighth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. CONGER WILLIAMS: In summary, this is the case of a sixty-seven-year-old man who came in with a history of progressive dyspnea and edema

and died two months later in a state of considerable fluid retention, in spite of fairly intensive therapy directed against it. It seems obvious that there are three main features. One is heart disease; another is the question of liver disease; and the third is diabetes, which we know that he had. Can all these findings be explained on a diagnosis of heart disease alone, and if so, what was the etiology? I believe that I can answer the first question but not the second.

It seems to me that, from the evidence at hand, all the findings described here cannot be explained by a diagnosis of heart disease alone. One of the greatest discrepancies is the finding of a venous pressure of 16 mm. (just above normal), with ascites and edema of the feet and ankles and so forth. Another feature that is a little unusual for heart disease alone is the appearance of ascites, presumably before the ankle edema. At any rate, when the patient first came in, ankle edema was slight and ascites quite well marked. That may be seen in cases in which the venous pressure is high, as in constrictive pericarditis or tricuspid disease, but in the ordinary course of congestive heart failure, especially that progressing from the left to the right side of the heart, such a sequence of events is unusual. The liver size too seems out of proportion to the venous pressure if one can credit the one measurement. Although this was taken at a time when the signs of fluid retention were quite marked, very likely we have another complication to consider. At this point I should like to ask the radiologist whether or not he thinks that the heart shadow was particularly enlarged.

DR. LAURENCE L. ROBBINS: Without much question in this film, which apparently was taken at the time of the first admission, the heart shows definite left ventricular enlargement. The area of calcification that is described in the note I presume is this area here, which is perfectly consistent with calcification in the aortic valve. One cannot say from the films alone that it was definitely within the heart, but it probably remained within the heart during fluoroscopy. These films, taken some three months later, are consistent with congestive failure.

DR. WILLIAMS: Do you think that the heart shadow is large?

DR. ROBBINS: There is slight to moderate enlargement.

DR. WILLIAMS: That may be an important point in making a decision about the underlying disease. It seems to me that the heart shadow should have been larger if this much fluid retention resulted from heart disease alone. Of course in a young person one should always think of mitral stenosis, with or without tricuspid disease, to account for an apparently predominant right-sided heart failure. In an elderly patient, such a diagnosis is possible but much less likely, and in this case I shall have

to throw it out. The necessary murmurs are not present, and the x-ray findings do not suggest mitral disease. High-grade tricuspid disease is hardly ever seen in the absence of mitral disease, except in rare congenital cases. It seems fairly obvious that there was some involvement of the heart. We have cardiac enlargement and a definite systolic murmur to back up that supposition, and the electrocardiographic changes are also indicative of heart disease, especially in the presence of significant arrhythmia, both flutter and fibrillation.

What is the etiology of the cardiac lesion? The murmur suggests aortic stenosis. Calcereous aortic stenosis usually occurs at this patient's age. Apparently the aortic second sound was heard, as it may be even in the presence of a fairly high degree of aortic stenosis. If an attempt is made to explain this whole picture on that basis, I should be happier about not hearing an aortic second sound, because the degree of aortic stenosis would need to be great, unless there was a complicating disease of the myocardium in addition. Coronary heart disease is a good possibility, yet one would not expect to find extensive myocardial involvement in the absence of previous infarction. Certainly from the history and the electrocardiogram there is no evidence that such an episode had ever taken place. So I cannot say much about the etiology of the heart disease, beyond saying that I think the patient probably had aortic stenosis.

How about liver disease? First of all, he had a good and a prolonged alcoholic history, and the laboratory tests are in keeping with the diagnosis of cirrhosis. The high grade of bromsulfalein retention and the positive cephalin-flocculation test, in the absence of any evidence of biliary obstruction, are certainly in favor of a diagnosis of cirrhosis. The liver size is also in keeping, and I think that I can explain the ascites better by assuming that the patient had a complicating liver disease. One often hears the clinical statement to the effect that when ascites develops in cirrhosis the liver must be small, but that is not always so.

How about other possible causes of the edema? We know that the serum protein, at least the total protein, was normal throughout. The albumin-globulin ratio was never more than slightly abnormal. Could the patient have had an obstruction of the inferior vena cava? There is no evidence of such an episode, and it would not explain the liver enlargement.

There is one other disease that must be considered, namely, hemochromatosis. This man presumably had liver disease, probably cirrhosis, in the presence of mild diabetes and cardiac involvement, with enlargement of the heart and at least some cardiac failure. To my knowledge hemochromatosis is almost never seen without pigmentation of the skin, but in one of these conferences anything can happen. I should like to ask Dr.

Castleman if any statement was made about skin pigmentation.

DR. BENJAMIN CASTLEMAN: No.

DR. WILLIAMS: In this stage of the disease one would almost certainly expect to see pigmentation of the skin. I just mention hemochromatosis as a possibility. It may produce destructive myocardial lesions as a reaction to the presence of pigment deposited in the heart muscle.

My final diagnoses are aortic stenosis, probably calcareous, cardiac enlargement, congestive heart failure, alcoholic cirrhosis of the liver, diabetes mellitus and, possibly, hemochromatosis.

DR. JOSEPH C. AUB: The quantity of ammonium chloride given was small (3 gm.) for the amount of edema. Maybe it was not effective so far as diuresis was concerned. Also, I do not believe that fluid in the chest rules out the possibility of cirrhosis. A good many of our cirrhotic patients have fluid in the right side of the chest. I do not know why.

DR. WILLIAMS: I meant to mention the fact that the presence of fluid in the chest is not against heart failure or cirrhosis.

A PHYSICIAN: Would there be any retention in fluid?

DR. WILLIAMS: Yes, more or less retention.

DR. PAUL D. WHITE: As I remember the story there seemed to have been hardly enough dyspnea to explain chronic left-sided, followed by chronic right-sided, heart failure. Is that true?

DR. WILLIAMS: He had dyspnea for a year. It is not described in great detail. I do not know whether it was present all the time.

DR. WHITE: To have cardiac cirrhosis one must have a lesion resulting in marked right-sided heart failure, which usually follows an extremely chronic degree of left-sided heart failure. Since that was not striking in this case, cardiac cirrhosis would seem less likely than alcoholic cirrhosis.

DR. WILLIAMS: I think constrictive pericarditis can be ruled out by the electrocardiogram as well as by the venous pressure.

CLINICAL DIAGNOSES

Calcereous aortic stenosis.
Cardiac hypertrophy.
Portal cirrhosis of liver.
Diabetes mellitus.

DR. WILLIAMS'S DIAGNOSES

Aortic stenosis (calcareous).
Cardiac enlargement.
Congestive failure.
Cirrhosis of the liver (alcoholic).
Diabetes mellitus.
Hemochromatosis?

ANATOMICAL DIAGNOSES

Rheumatic heart disease.
Endocarditis, chronic, rheumatic, of mitral and aortic valves.

- Calcareous aortic stenosis.
- Cardiac hypertrophy and dilatation.
- Pulmonary congestion and edema.
- Hydrothorax, right.
- Ascites.
- Peripheral edema, moderate.
- Chronic passive congestion.
- Cirrhosis of liver, cardiac, slight.
- Chronic thyroiditis (Riedel's struma).

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The autopsy on this man showed an enlarged heart, weighing 550 gm.

There was no disease of the tricuspid or pulmonary valves.

We found 500 cc. of straw-colored fluid in the abdomen and 1000 cc. in the right chest. The lungs showed congestion and some edema. The liver was enlarged, weighing a little under 2000 gm., and in gross showed little if any evidence of cirrhosis, perhaps a fine granularity but certainly not a portal cirrhosis. There was distention of the central veins grossly, and microscopically there was dilatation of all the sinusoids, with narrowing of the liver cords and a little cellular infiltration in places (Fig. 2), a picture characteristic of a fairly severe

FIGURE 1. Photograph of the Heart.

Note the calcareous stenosis, as well as the shortening and thickening of the chordae tendineae of the aortic leaflet of the mitral valve.

There was rheumatic involvement of the mitral valve but not enough to produce a severe stenosis. The chordae tendineae were shortened and thickened, and the leaflets themselves were fibrotic. The aortic valve also showed rheumatic involvement (Fig. 1). There was interadherence of the cusps of the aortic valve for a distance of almost 1 cm. from their commissures. In addition there were calcareous masses on the aortic side of the valve in and above the sinuses of Valsalva and also on the endocardial side of the valve. So we have an aortic calcareous stenosis, definitely rheumatic this time, to account for the enlarged left ventricle.

degree of chronic passive congestion. There were scattered foci of early fibrosis, and I believe that there is sufficient evidence for a diagnosis of early cardiac cirrhosis. It is quite unusual to have this much cirrhosis with the first attack of heart failure. Cardiac cirrhosis usually occurs only after two or three attacks, whereas this patient, at least from the history, had had just one.

DR. WHITE: He may have had more prolonged disease than we know about.

DR. CASTLEMAN: Another interesting finding in view of the diabetes was a severe chronic thyroiditis

of the Riedel struma type. There must have been little activity of the thyroid gland. With severe thyroid impairment one would ordinarily expect a low blood sugar rather than diabetes. Is that not so, Dr. Aub?

DR. AUB: The fasting blood sugar ought to be normal. The sugar curve might be abnormal in hypothyroid disease. Hyperthyroidism has a blood-sugar curve reminiscent of diabetes, but it starts off with a normal blood-sugar level.*

DR. HOWARD B. SPRAGUE: Do you believe that the alcoholic history had anything to do with

In reading this history I could not differentiate, but with the liver findings and with aortic stenosis of rheumatic origin I thought that he must have had cardiac cirrhosis, because on referring to Dr. White's* book I find the statement, "Cirrhosis of the liver due to heart disease, although infrequent, is most commonly noted in those who have had chronic or recurrent congestive failure secondary to rheumatic heart disease."

DR. WHITE: I think this is a case in point in which we cannot distinguish clinically. Although Dr. Castleman found no alcoholic cirrhosis, alco-

FIGURE 2. Photomicrograph of the Liver.

making the liver hypersensitive to chronic passive congestion?

DR. CASTLEMAN: I do not believe so, because if there was any evidence of alcoholism in the liver we should have seen a fatty change with perhaps hyaline granules in some of the liver cells or a little portal cirrhosis. We found nothing to suggest it.

DR. WHITE: If a patient has had enough congestion, I suppose that he might have impairment of function that would resemble primary liver disease.

DR. WILLIAMS: One point that might have settled the thing from the beginning would have been an accurate observation on the state of the neck veins. A good clinical observation of neck veins is almost as good as direct measurement of the venous pressure. Often there is an early increase in venous pressure. A statement is made in the history, but the observation was made later. I wonder whether the degree of congestion was out of proportion to the size of the heart. There seems to have been a terrific amount of congestion for a moderately enlarged heart.

A PHYSICIAN: How would you distinguish between cardiac cirrhosis and portal cirrhosis at the bedside?

holism may possibly have been something of a factor in preparing the field for the cirrhotic change when his heart finally failed.

DR. SPRAGUE: Of the hundreds of cardiac cases that we see here, we encounter this picture only rarely.

A PHYSICIAN: What about the spleen?

DR. CASTLEMAN: It was not enlarged, weighing about 200 gm. It certainly could not have been felt and probably could not have been shown by x-ray to be enlarged.

A PHYSICIAN: Would the finding of esophageal varices have helped?

DR. CASTLEMAN: Yes; that would be a differentiating point between portal and alcoholic cirrhosis. They apparently were not observed.

DR. REED HARWOOD: Was there coronary sclerosis or evidence of disease in the myocardium?

DR. CASTLEMAN: There was slight narrowing of the coronary arteries, but no evidence of scarring of the myocardium.

CASE 30462

PRESENTATION OF CASE

A seventy-one-year-old housewife was admitted the hospital for study.

For many years the patient had had intermittent abdominal pain. Fifteen years before entry, following an attack of cholecystitis, a cholecystectomy and probably a choledochostomy were done, with considerable immediate relief. She continued, however, to have intermittent attacks of vomiting and epigastric pain associated occasionally with dark urine and once with jaundice for a day. Four months prior to admission she began to have bouts of crampy epigastric pain on getting up in the morning, so that she was forced to go back to bed several hours. These occurred about once a week. In the next two months the pain increased in severity but never radiated to the back or to the shoulder. There was occasional vomiting of bile-stained material. She gradually became disabled. Three weeks before admission she entered hospital in another city. A gastrointestinal series taken there was said to have shown a diaphragmatic hernia. Plain films of the abdomen showed gas in the large intestine. There was some improvement in the abdominal pain, but she was referred here for further study. She had been constipated for years, and there had recently been no change in the stools.

Physical examination showed a well-nourished, slightly pale woman in no discomfort. The heart was not enlarged. Apical and aortic (Grade I) systolic murmurs were heard. The lungs were clear, except for occasional squeaks. The abdomen was distended. Peristalsis was active and of normal rhythm. In the epigastrium there was tenderness to deep pressure, but no masses were palpable. The lower extremities were edematous up to the lower thigh.

The blood pressure was 125 systolic, 80 diastolic. The temperature was 98.6°F., the pulse 75, and the respirations 20.

The white-cell count was 9100, with 12 gm. of hemoglobin. The nonprotein nitrogen was normal, and the serum protein 5.8 gm. The specific gravity of the urine was 1.010; it showed a + test for albumin, and the sediment contained 30 white cells and 3 red cells per high-power field. A blood Hinton test was negative. A van den Bergh test was too low to read. Plain films of the abdomen showed a considerable amount of gas in the colon and a moderate amount in the epigastric region, probably in the stomach; no definitely dilated loops of small bowel were visible.

The patient was given daily intravenous fluids. A Miller-Abbott tube was passed with some difficulty to the ligament of Treitz. The following day about 15 cc. of barium was injected through the tube, which by that time was in the lower ileum.

and filled a nondilated loop. Peristalsis was not active, however, and the barium did not pass along the bowel during the short period of fluoroscopy. A film taken one hour later showed the barium in the cecum. No dilated loops of small intestine were visible. A twenty-four-hour film showed all the barium in the right side of the colon. No evidence of intestinal obstruction was seen.

The patient continued to have abdominal discomfort and vomited everything she ate. On the fifth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD HAMLIN, JR.: We are asked to discuss a case of crampy epigastric pain, vomiting and abdominal distention in an elderly woman with an old history of gall-bladder disease whose physical examination was essentially normal except for edematous legs. If there is a clue about what part of her anatomy was at fault, I fail to find it, and the laboratory work offers no help. Perhaps the attempt to fill the small intestine with barium indicates that the clinicians' chief interest was in the small bowel. One must assume that they knew more about her than we do, for I am certain that I should not operate on anyone with the facts at hand. Assuming, then, that something was at fault with the small intestine, — the location of pain and persistent vomiting tend to bear that out, — what should we consider?

The story suggests that she did not have obstruction, but rather impediment to the passage of intestinal contents. A band or adhesion is statistically the likeliest cause of this.

We know that the patient had had an operation on the gall bladder. Adhesions of the duodenum to the gall-bladder bed with angulation are not at all infrequent, but the clinicians appear not to have been interested in that region, since they injected barium into the lower ileum. Certainly an adhesion of the small intestine below the duodenum to the gall-bladder bed is unusual. What else could have been at fault? Tumors of the small bowel occur and may have obstruction as their first symptom. Practically any type of tumor could be considered and not ruled out. Furthermore, interference to the circulation of the bowel at this patient's age is not rare.

Mesenteric venous thrombosis is a possibility, and it could perhaps best explain the apparent atony of the small bowel observed under the fluoroscope. A four-month history, however, is unusual for this condition. We are told that the pain at no time radiated to the back, which is unlikely when the mesentery is involved. A complication of a Meckel's diverticulum might be considered. It seems pointless to continue with a catalogue of all the minor possibilities that can and probably should be thought of in connection with this patient.

Since a diagnosis is asked for, I shall say that this patient had venous thrombosis of a segment of mesentery of the small bowel, probably in the lower jejunum or upper ileum, which was not sufficient to cause necrosis of the bowel but which did prevent normal peristalsis and so produced the symptoms.

CLINICAL DIAGNOSIS

Postoperative adhesions.

DR. HAMLIN'S DIAGNOSIS

Mesenteric venous thrombosis.

ANATOMICAL DIAGNOSIS

Carcinoma of pancreas, with peritoneal metastases.

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: As Dr. Hamlin has indicated, the available clinical data on this patient were extremely meager, but the case does bring up the question of a differential diagnosis of atony of the small bowel with abnormal peristalsis. Dr. Hamlin chose venous thrombosis; the surgeon in charge of the patient inclined toward adhesions caused by the previous gall-bladder operation. Another cause of disturbed peristalsis is carcinomatous infiltration of the visceral peritoneum of the small bowel, and that is what this patient had. There were numerous small tumor nodules over the small bowel, one of which was biopsied and proved to be adenocarcinoma. The primary tumor was a baseball-sized mass in the head of the pancreas. A liter of ascitic fluid was aspirated before the abdomen was closed.

We have since heard that the patient died five months later.

THE FREEDOM

A YOUNG infantryman, writing from the Italian front last winter, gave his views on the problem of promised freedoms. The four freedoms, according to this concept, can be included in the one freedom — freedom of thought in its broadest sense. He wrote: "The other three are subsidiaries. . . . Freedom of religion is but a phase of direct thought. Hatred and fear are curses which can be lifted only by 'right thinking.' . . . Freedom of thought should be interpreted in a very positive light — the necessity for true thought, and it should imply the forward step from freedom-to-think-as-you-please to the compulsion to seek out the truth." This foxhole philosophy arose out of a soldiers' discussion of war ideals and issues; it does its bit

toward making us believe that the soldier, too, realizes his stake in the war and the peace, and sees no advantage in risking his own life in combat unless some considerable portion of the human race is going to benefit by his sacrifice. Under the circumstances there is something either stupid or sinister in the recent legislative attempt to deny political information to the soldier after giving him the vote; to deny him, in other words, that very freedom of thought for which he had been given to understand that he is fighting.

Freedom of thought and its more concrete ramifications, such as freedom of speech, freedom of the press and freedom to worship, are actually highly elusive qualities that must be wooed and fought for and cherished, over and over again. No ruler, however altruistic, however freedom-loving in principle, can hold power long without putting restrictions for others on the very freedom that he professes to love so well. A subversive tendency is being shown in our own government, where, it is said, various department workers are forbidden to question department policies, unless they care to run the risk of losing their jobs. Freedom of thought cannot be tolerated, apparently, on a one-track road, and no desire for the truth, however burning, can be permitted to interfere with departmental expediency.

Everywhere, on a desperately contested battle front, we are fighting to protect our basic freedom against assaults from without. We must not forget, however, that the "compulsion to seek out the truth" must be constantly protected from those who would seek to destroy it from within — even from some who, with apparent sincerity, give it their daily blessing.

GLOBAL EPIDEMIOLOGY

PERHAPS nothing is a better illustration of the intricacies and all-inclusiveness of modern medicine than one of many problems that faced the Preventive Medicine Service of the Office of The Surgeon General prior to and after the entry of the United States in World War II. This particular problem concerned the assembling, evaluation and dissemination of data regarding medical, health and sanitary conditions for all localities in which military

forces might be stationed. Because of the global character of the conflict it soon became apparent that information should be available for every corner of the world, varying from Arctic regions to the tropics, from arid deserts to humid jungles and from areas with adequate public-health control to those in which such facilities were lacking, indeed in which the dangers of disease were much greater than those of combat.

The Medical Intelligence Division of the Preventive Medicine Service was established in June, 1941, to handle the problem, and this division, to which two officers were originally assigned, has now grown to comprise eleven officers, five civilians of professional grade and a clerical staff of fifteen. Surveys covering one hundred and ninety areas have been prepared. The data included are as follows: geography and climate; public health, including health services, water supplies, sewage disposal, insects and animals, poisonous plants and foods, food and dairy products, and miscellaneous problems of sanitation; medical facilities, including hospitals, medical personnel and medical institutions; diseases, arranged according to mode of spread; a summary; and a bibliography. The enormity of the task of assembling these facts is apparent, particularly since many of them could be obtained only from obscure sources or by personal interviews. Equally clear is their value not only to the military forces but also to those interested in the broad aspects of preventive medicine, and the publication of these surveys, necessarily with the deletion of matters of military significance, should be enthusiastically welcomed.

The first volume of *Global Epidemiology** consists of two parts: the first includes India and the Far East, and the second, the Pacific area. The listed authors, Brigadier General J. S. Stevens, chief of the Preventive Medicine Service, Office of The Surgeon General, United States Army, Lieutenant Colonel T. F. Whayne, Lieutenant Colonel G. W. Anderson and Major H. M. Hadock, are naturally those who have been largely responsible for the conception and completion of the undertaking.

*Simmons, J. S., Whayne, T. F., Anderson, G. W., and Hadock, H. M. *Global Epidemiology: A geography of disease and sanitation*. Vol I 504 pp. Philadelphia: J. B. Lippincott Company, 1944.

With the appearance of the three subsequent volumes, which will cover surveys of countries and areas in Africa, Europe, the Near East and the Western Hemisphere, data will be available that should be of incalculable value in the period of global trade and rapid transportation that is certain to follow the termination of war.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

BRUCE — Daniel A. Bruce, M.D., of Quincy, died November 5. He was in his eighty-second year.

Dr. Bruce received his degree from McGill University Medical School, Montreal, in 1892. He was a member of the staff of Quincy Hospital for many years, and was a former president of the Norfolk South District Medical Society.

TRASK — Harry W. Trask, M.D., of West Boylston, died November 5. He was in his sixty-fourth year.

Dr. Trask received his degree from the University of Vermont College of Medicine in 1904. He was chief obstetrician at Holden Hospital and school physician in West Boylston many years. He was a member of the American Medical Association.

BOOK REVIEWS

Rehabilitation of the War Injured: A symposium. Edited by William B. Doherty, M.D., and Dagobert D. Runes, Ph.D. 8°, cloth, 684 pp., with 229 illustrations and 17 diagrams. New York: Philosophical Library, Inc., 1943. \$10.00.

Is it possible to make a treatise by bringing together fifty-one essays culled from nineteen current periodicals and two books, American, British and Russian, without delineating the respective fields to be covered and utterly without editorial streamlining? This book does not give an affirmative answer. It contains articles of widely different method and merit, which unfortunately often overlap and equally often leave gaping hiatuses.

The first section, comprising ten essays on neurology and psychiatry, is much the best, as would be expected from the distinction of some of its authors. The section on reconstructive and plastic surgery would be inadequate as an aid to the surgeon confronted by these problems. Several of the topics, such as harelip and cleft palate, have no relation to war injuries, and others are frankly in the field of the beauty parlor rather than that of the military general hospital. In the section devoted to orthopedics, the articles on amputations and limb fitting are useful, but one on leg lengthening seems hardly germane, and the transplantation of the great toe to replace the thumb, "with restoration of all forms of sensibility," by the incredible Russians seems of dubious practical value. Several articles on the organization and administration of rehabilitation centers among the British may prove useful. The next section, consisting of fourteen contributions on occupational therapy and vocational guidance, is marred by the inclusion of much scarcely relevant matter, such as that concerning civilian pulmonary tuberculosis in England. Perhaps the most timely contribution is the last, entitled "Vascular and Neurologic Lesions in Survivors of Shipwreck."

The volume is well printed and bound, but it is impossible to speak so favorably of the illustrations, most of which are miserably reproduced, and many of whose labels can scarcely be deciphered with the aid of a magnifying glass. Furthermore, the proofreading could have been done with more care.

It seems to the reviewer that, although there are many excellent and informative passages in this book, the seeker for guidance in most of the problems that it treats but does not cover will be obliged to turn to other sources.

Hundred Years of Medicine. By C. D. Haagensen, M.D., Wyndham E. B. Lloyd. 8°, cloth, 444 pp., with 42 illustrations. New York: Sheridan House, 1943. \$3.75.

This is an impressively instructive book for the beginning medical student, as well as for the layman. It is absorbing and reflects the judicious attitude of the authors in their effort to trace important medical advances from their origin rather than attempting to survey the whole field of medicine in strict chronological order. Dr. Haagensen, surgeon and pathologist at Columbia University School of Medicine, and Dr. Lloyd, a specialist in public health in England, deal with their material under four sections.

The first section provides the reader with an insight into the state of knowledge that existed a hundred years ago, by scussing briefly the origin of medicine, the theories of medicine in the eighteenth century, the state of hospitals, the military conditions, and the organization and education of the medical profession. The second section, covering medical science during the last hundred years, presents a keen analysis of the germ theory and progress in chemotherapy, vitamin therapy and in knowledge concerning tuberculosis, pernicious anemia, diabetes, diseases of the heart and nephritis. The third section, dealing with surgery during the last hundred years, begins with a discussion of McDowell's ovariectomy and goes on to consider topics such as anesthesia, the conquest of surgical infection, surgical shock, obstetrics and gynecology, orthopedics, neurosurgery, thoracic surgery and radium therapy. The fourth section, concerning the new social aspects of medicine, points out the significance of the ageing of the population since the turn of the century. The authors come to the paradoxical conclusion that although the nineteenth century was one of phenomenal medical progress, the conquests of the diseases of youth that were achieved have left us with health problems even more difficult than those before, — both from the medical and the economic point of view, — namely, the degenerative group of diseases of advancing age, such as heart disease, cancer, cerebral hemorrhage and nephritis. In the final chapter, "The Doctor's Dilemma," the question is raised how best to utilize the vast modern armamentarium of medical knowledge for the benefit of society, and in seeking an answer to this question the authors deal with the challenges offered by the reform in medical education, specialization, the costs of medical care and medical-insurance systems, both abroad and in America. There are forty-two excellent illustrations, a useful bibliography and a good index.

This book should be read by all medical students who wish to gain an appreciation of the facts of disease to which they can attach their fundamental knowledge of anatomy, physiology, pathology and biochemistry. The authors deserve congratulations on an admirable work for the benefit of the layman and the medical profession.

Microscopic Technique in Biology and Medicine. By E. V. Cowdry, Ph.D. 8°, cloth, 206 pp. Baltimore: The Williams & Wilkins Company, 1943. \$4.00.

The purpose of this extraordinarily useful book is "to extend the horizon by exposing in an introductory way a few of the many opportunities awaiting workers in biology and medicine interested in the minute structure of living things." The author, well known as a brilliant scientist, devotes ten pages to a succinct, profitable discussion of choice of methods, as a kind of menu. There follow a few pages on the organization of the laboratory and the standardization of stains. Then, in alphabetical order, come a list of stains, techniques, chemical procedures, apparatus and numerous other valuable items, all briefly discussed and carrying easily available bibliographic references. This book should be a *sine qua non* on the shelves of all medical libraries; its value can only be proved by its constant use.

Blood Supply of the Visual Pathway: A monograph. By Calvin M. Kershner, M.D., M.S. (ophth.). 8°, cloth, 160 pp., with 33 illustrations. Boston: Meador Publishing Company, 1943. \$5.00.

This small monograph attempts to gather together in one place in a systematic manner many of the essential facts

displayed in a wide literature, analyzing and correlating the pertinent information most valuable to the ophthalmologist. The book is divided into two parts; the first covers the general arterial supply and venous drainage, and the second deals with the detailed blood supply and venous drainage of each section of the visual pathway.

There is little about the illustrations to commend them, and the book loses greatly in value from the fact that the author did not include an index.

Human Constitution in Clinical Medicine. By George Draper, M.D., C. W. Dupertuis, Ph.D., and J. L. Caughey, Jr., M.D. 8°, cloth, 273 pp., with 29 illustrations and 30 tables. New York: Paul B. Hoeber, Incorporated, 1944. \$4.00.

Twenty years ago Dr. Draper wrote a book *Human Constitution*. His idea was to apply to clinical medicine the technics of measurement used by anthropologists and in this fashion to study as scientifically as possible the relation of human morphology to disease.

He drew some interesting conclusions from his preliminary work. He thought that certain types of people were likely to develop certain types of disease: the person likely to have gallstones, for instance, was measurably separable from the one likely to develop gastric or duodenal ulcer. He acknowledged that he was describing only the commencement of a program of investigation that he expected to elaborate and stated that eventually he hoped to correlate anthropometric studies on sick people with their physiologic, immunologic and psychologic reactions to such diseases as they were compelled to endure.

This new book is written in collaboration with two other authors, but is in reality an extension of the first. Here, Dr. Draper lays less stress on the methods of measurement employed and much more on psychology. He describes a number of patients constitutionally liable to develop the diseases they proved to have, and through them he attempts to defend further the idea expressed in the first volume, namely, that disease potentially may be a secondary sex characteristic since persons suffering with diseases most commonly encountered in the opposite sex often show constitutional variations approaching the norms for the opposite sex. He carries along his argument ingeniously and graphically. Throughout all his discussion he lays great emphasis on the need in clinical practice for the doctor always to understand how his patients feel and what sort of human beings they are.

The new book was written largely for the benefit of medical students. They will find it readable and stimulating. More mature clinicians will find much in it that is worth while. For underneath a camouflage of newly coined words is repeated a medical truism attributed to old Dr. Parry, of Bath, which, no matter how it is disguised, continues as significant as when it was first propounded: "It is just as important to know what sort of patient has a disease as to know what sort of disease the patient has."

Health and Hygiene: A comprehensive study of disease prevention and health promotion. By Lloyd Ackerman, Ph.D. 8°, cloth, 895 pp., with 59 illustrations and 27 tables. Lancaster, Pennsylvania: The Jacques Cattell Press, 1943. \$5.00.

The author has attempted to provide a book on disease prevention and health promotion "that will appeal to mature, inquiring minds in all circles: nonscholastic as well as scholastic, lay as well as professional, and legal, political, engineering, social service, journalistic, pedagogical and religious as well as medical." This is necessarily a most difficult accomplishment, and it is doubtful whether all these groups will be interested in his efforts. The bibliography is excellent and extensive. The physician might well be interested in this if not in the text. A perusal of the index shows that many diverse phases of medical science are discussed, ranging from the life work of Mary Baker Eddy to penicillin. Some subjects are discussed in detail, others are rapidly reviewed. Diabetes is covered by ten lines, the cancer problem by thirteen pages, and mental hygiene by one hundred and forty-five pages. There is much that could be considered controversial in the work, which makes it challenging

to the interested reader, but those desiring information on certain subjects will be disturbed after reading all sides of the given question to find no solution to the problem. It is definitely not for a casual reader, and although written in an interesting style, the arrangement is such that it requires frequent skipping from one part of the book to another in order to clarify a subject. Public health has largely been omitted. This is so intimately connected with personal hygiene that one would question the omission.

The book is divided into ten sections as follows: "Introduction," "The Evolution of Health Concepts and Health Practices," "The Evaluation and Importance of Health Concepts and Health Practices," "Parasitism and Hypersensitiveness," "Hygiene of the Mouth," "The Hygiene of Nutrition," "Hygiene of the Emotions and the Intellect," "The Hygiene of Mating," "Exogenous Poisons" and "Physical Agents and Their Relations to Health."

Some might wonder why cancer was included under "exogenous poisons," whereas others would question the advisability of including the results of surveys on sex practices in a volume that in the preface is tentatively suggested as a textbook.

NOTICES

SUFFOLK DISTRICT MEDICAL SOCIETY

The fall dinner of the Suffolk District Medical Society will be held on Saturday, November 18, at the Harvard Club of Boston, 374 Commonwealth Avenue, Boston. A social hour beginning at 6:00 p.m. will be followed by dinner in Harvard Hall at 7:15. His Excellency, Leverett Saltonstall, will speak on the topic, "Medical Social Security," and Dr. Roger I. Lee on "Health Insurance?"

It is urged that doctors bring their wives and particularly that the wives of all doctors absent in the service, whether or not the doctor is a member of Suffolk Society, be invited by members as their guests. Each member who sends to the treasurer with his own application the names of such service wives will receive free tickets for them. The tickets, \$3.00 each, must be purchased in advance by sending cash or a check to the treasurer, Dr. Richard S. Eustis, 319 Longwood Avenue, Boston 15. Other members of the Massachusetts Medical Society may apply.

SOUTH END MEDICAL CLUB

A regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, November 21, at 12 noon. Dr. William P. Murphy will speak on the subject "Vitamins."

Physicians are cordially invited to attend.

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held on Monday, November 20, at 8:15 p.m., at the Boston Medical Library.

The entire program will be devoted to a symposium "Treatment of Subacute Bacterial Endocarditis with Penicillin."

PROGRAM

Experience at the New Haven Hospital. Drs. Jessamine Goerner and Arthur Geiger.

Experience at the Massachusetts General Hospital. Drs. Marion W. Mathews and Paul D. White.

Experience at the Peter Bent Brigham Hospital. Drs. Cutting B. Favour, Charles Janeway, John G. Gibson and Samuel A. Levine.

Experience at the Boston City Hospital. Dr. Maxwell Finland and associates.

Experience at the House of the Good Samaritan. Drs. Benedict F. Massell and Mary Meyeserian.

Discussion. Dr. Chester S. Keefer.

NEW ENGLAND ROENTGEN RAY SOCIETY

The next meeting of the New England Roentgen Ray Society will be held at the Harvard Club on Friday, November 17. There will be an x-ray conference at 4:30 p.m. 8:00 p.m. the following program will be presented:

Pulmonary Infarction.

Roentgenologic Appearance. Dr. Laurence L. Robbins
Clinical Features and Treatment. Dr. Robert R. Lint
Intrapulmonary Lymphatic Spread of Metastatic Carcinoma.

Roentgenologic Appearance. Dr. H. Peter Mueller.
Pathology. Dr. Ronald C. Sniffen.

NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

The sixteenth annual meeting of the New England Obstetrical and Gynecological Society will be held at the Harvard Club of Boston on Wednesday, December 6.

AUSTEN RIGGS FOUNDATION

The Austen Riggs Foundation Medical Advisory Board commemorating the twenty-fifth anniversary of its hospital by holding the annual meeting this year at the Academy of Medicine in New York City on Wednesday, November 21 at 3:30 p.m. Dr. Lawrence S. Kubie will present a paper on the problems of brief psychotherapy and the training of therapists, particularly the role of the small sanitarium at hospital in such a program. A discussion will follow by Brigadier Rees, of London, the Salmon Lecturer, Major General Chisholm, of Ottawa, and others.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The next written examination and review of case histories (Part I) for candidates will be held in various cities of the United States and Canada and by special arrangements at Army and Navy stations on Saturday, February 3, 1945, at 2:00 p.m. Candidates who successfully complete the Part I examination proceed automatically to the Part II examination held later in the year. All applications for this year's examinations must be in the office of the secretary by November 15, 1944.

Arrangements will be made, so far as is possible, for candidates in military service to take the Part I examination (written paper and submission of case records) at their places of duty, the written examination to be proctored by the commanding officer (medical) or by a medical officer designated by him. Material for the written examination will be sent to the proctor several weeks in advance of the examination date. Candidates in military service who wish to do so may send their case records in advance of the examination date to the office of the secretary. All other candidates should present their case records to the examinee at the time and place of taking the written examination.

The Office of The Surgeon-General of the United States Army has issued instructions that men in service eligible for Board examinations be encouraged to apply and that they may be ordered to detached duty for the purpose of taking these examinations whenever possible. The Office of The Surgeon-General of the United States Navy presumably takes a similar attitude on this matter.

The place of the Board's Part II examination in May or June, 1945, has not yet been decided, but it is likely to be held in that city nearest to the largest group of candidates. The exact time and place will be announced later.

If a candidate in service finds it impossible to proceed with the examinations of the Board, so that his plans are thus interrupted, deferment of parts of these without time penalty will be granted under a waiver of the published regulations covering civilian candidates.

For further information and application blanks, address Dr. Paul Titus, Secretary, 1015 Highland Building, Pittsburgh 6, Pennsylvania.

PRIMARY ATYPICAL PNEUMONIA OF UNKNOWN ETIOLOGY*

SVEN GUNDERSEN, M.D.†

HANOVER, NEW HAMPSHIRE

In the United States and in many other regions throughout the world from which adequate medical reports are available, there appears to have been, during the last few years, an increased incidence of an unusual form of pneumonia, the etiology of which is unknown. It has been refractory to the methods of treatment specific for bacterial pneumonias.

Many papers on this subject have appeared in the recent medical literature. In a thorough review published in the *Journal* about two years ago, Finland and Dingle,¹ in addition to summarizing the clinical, laboratory, x-ray and pathologic features of the disease, emphasized certain other points. They state that this is probably not a new disease, inasmuch as a description of a closely similar malady dates back seventy-two years; that the etiology is unknown and that it is therefore unwise to assume that the etiology is a virus; that as a result the diagnosis is likely to be at best uncertain; and that most etiologic studies seem to exclude any relation of the disease to other forms of pneumonia of known virus etiology, such as ornithosis — including psittacosis — and influenza. Such studies, furthermore, show that the disease probably bears no relation to Australian or American Q fever, or to similar diseases with pneumonic lesions of rickettsial etiology. It is quite possible that several etiologic agents are involved, and that therefore so-called "virus pneumonia" is a syndrome rather than a true entity. For this reason, it becomes all the more important to analyze carefully and become thoroughly acquainted with the clinical and laboratory features as they are revealed at present.

Primary atypical pneumonia has been described in most studies as having influenzalike symptoms, often associated with evidence of mild upper respiratory infection, few physical findings, which are usually slow in making an appearance, and variable but disproportionately extensive lesions as shown by x-ray examination. Other laboratory tests have

been inconsistent and disappointing. Periods of fever and disability have generally been long, making the illness of considerable economic importance.

Complications and sequelae have been described as mild and trivial. Deaths in most series have been absent or very few. In the scarce reports of cases that have come to autopsy, patchy, hemorrhagic, interstitial bronchopneumonia, associated with acute bronchitis and bronchiolitis, has been found. Areas of atelectasis and emphysema with small patches of red or gray consolidation have been described. The main microscopic feature has been a hemorrhagic or mononuclear-cell exudate in the alveoli. No inclusion bodies have been noted.

A few of these cases began to appear at the Hitchcock Hospital and the Dartmouth College Infirmary in 1938, but by far the largest number have been seen there in the last two and a half years. The naval officers of the first indoctrination school were particularly often afflicted. Many cases in children and adolescents have come from summer camps. Excellent opportunity for close observation and study has been afforded in this group of patients because all of them have been hospitalized where x-ray and laboratory facilities could be freely used. All have been under the care of five physicians who have special interests in internal medicine or pediatrics.

From January, 1942, to February, 1944, inclusive, 162 patients with a final diagnosis of primary atypical pneumonia were in the hospital. In all of them there was a confirmation of the diagnosis of some sort of pneumonia by x-ray examination. Only 122 cases, however, including 3 fatal ones, 2 of which came to autopsy, were used for analysis in this study. The 40 rejected cases were considered unsuitable for various reasons. Sputum tests were inadequate in most of them; the clinical records were incomplete in a few; and some were doubtful cases, in which the pneumonia, on more detailed consideration, seemed likely to be bacterial or to be a complication of some other disease.

One hundred and eight of these 122 patients (88 per cent) were males. This percentage is not in

*Presented at the annual meeting of the New Hampshire Medical Society, Manchester, May 16, 1944.

†Instructor in physical diagnosis and medicine, Dartmouth Medical School; member of staff, Mary Hitchcock Memorial Hospital and Hitchcock Clinic.

accord with that of other reports and is probably explained by the high incidence of males in the community at the time. These men were living in crowded quarters and going through training that was strenuous and unusual. The youngest patient was three years old and the oldest seventy-nine; 101 patients were in the second or third decade of life. This is in keeping with other studies, which indicate that adolescents and young adults are particularly susceptible to this malady, in spite of the fact that there was a special age selection in this college community. The age incidences by decades were 2 in the first, 60 in the second, 41 in the third, 12 in the fourth, 4 in the fifth, and 1 each in the sixth, seventh and eighth.

Many of these patients were seen in the summer and fall of 1942, and even more in the winter of 1942-1943. It is interesting to note that no patient was admitted to the hospital in May or June of either year. The period of observation is too short to permit any conclusions, but there is at least a suggestion that the seasonal incidence is quite different from that of diseases due or related to the hemolytic streptococcus. The monthly incidence (Table 1)

TABLE 1. Monthly Incidence.

coincides closely with that in a series reported by Murray² from the Department of Hygiene, Harvard University.

The period of hospitalization varied from six to sixty-seven days, with an average of nineteen days. This was due in part to the fact that the patients in military service, of which there were many, had to be well along in convalescence before they could be dismissed.

The febrile period during hospitalization varied from one day to twenty-eight days, with an average of nine days. This average is a little higher than that of cases of pneumococcal lobar pneumonia in which the patients recover spontaneously without specific serum or sulfonamide therapy.

In reviewing the symptoms of these patients (Table 2), a few striking points became evident. Cough, headache, malaise and sore throat were the most frequent symptoms, in the order named. Shaking chills were relatively infrequent. Cough was often slow in development. In most cases it was explosive, hacking and distressing; in the average case it gradually became productive of small amounts of mucopurulent sputum. Of great im-

portance for the differential diagnosis was the complete absence of typical pleuritic pain and of "prune juice" or rusty sputum. Numerous other complaints were offered by a few patients, as indicated in the table. Dyspnea occurred in only 2 cases, but in both there was a fatal outcome.

The term "atypical pneumonia" is particularly appropriate in relation to the question of physical findings. Most patients had few signs and a minor

TABLE 2. Distribution of Symptoms

SYMPTOMS	NO. OF CASES
Cough	114
Headache	71
Malaise	58
Sore throat	50
Chills or chilliness	44
Coryza	32

Substernal ache (or tightness)	12
Fatigue	11
Anorexia	9
Aching eyes	8
Fever	7
Vomiting (or nausea)	5
Hoarseness	3
Dyspnea	2

proportion showed none whatever. Typical signs of consolidation were detected in less than one tenth of the patients, and came late in the course of the disease. Rales, either crepitant or musical, particularly after cough, were detected in 103 cases, but again usually appeared late. There was dullness in 34 cases, and increased vocal fremitus in 8. The breath sounds were diminished in 23 cases and otherwise changed in 11. It is worth emphasizing that no undoubted pleural friction rubs were felt or heard, nor was there ever any convincing evidence of collection of fluid in the pleural cavity. Generally speaking, most of the patients did not look particularly ill at any time, even when they had high fever. Usually, the pulse was relatively slow. Rarely was there cyanosis or abdominal distention. Herpes simplex was not reported. Slight to moderate inflammation of the nares and pharynx was apparent in most patients. The spleen was palpable for a few days in 2 cases.

The sputum was examined in every case, either by culture and typing of any pneumococci that could be isolated or by the gram-staining of smears followed by direct typing of the sputum if organisms morphologically resembling pneumococci were seen. Eighty-two cases showed many organisms in the cultures with no one of them predominating; the mixtures consisted chiefly of green-producing streptococci, staphylococci, pneumococci, *Micrococcus catarrhalis* and influenza bacilli. Hemolytic streptococci were present in 6 cases, usually in small numbers. Typable pneumococci were found in small numbers in only 4 of 77 cases examined for this purpose; these were types 3, 4, 8 and 23, respectively.

Blood cultures were done in 55 cases, and were reported as sterile in all but 1, in which contamination was suspect

The white-cell counts ranged from 3000 to 23,000. The average count was higher during the latter part of the febrile period than at the beginning of the illness or at the end of the period of hospitalization. The percentage of polymorphonuclear leukocytes averaged 77, and in most of the severely ill patients there was an increase in immature forms — in 1 case to 35 per cent.

Sulfonamides were given as a therapeutic and diagnostic test in 63 cases in adequate dosage, as judged by blood-level determinations, without any notable beneficial effect on the symptoms, fever or time of hospitalization. Fifty-eight of these patients received sulfadiazine, 4 sulfathiazole, and 1 sulfamerazine.

Complications and associated diseases occurring during the convalescent period were relatively few and mild. Sinusitis developed in 4 cases. Otitis media, chiefly catarrhal, occurred in 5 cases, and in all of them was successfully treated by x-ray therapy and other conservative measures. One patient — a child — with the symptoms and signs of meningitis had increased cells in the spinal fluid, chiefly lymphocytes, but no organisms could be isolated by smears or culture, and the clinical condition improved rapidly. There was mild jaundice in 1 case, and measles in 1.

Bronchiectasis as a late complication was proved by a lipiodol bronchogram in 1 case and was suspected in a second. Follow-up study of the latter case proved impossible because the patient was transferred to a Navy hospital.

As stated previously, the diagnosis of pneumonia was confirmed by x-ray examination in all cases. The right lung was involved in 54 cases, the left in 44, and both lungs in 24. The site of involvement was the lower lung field in 90 cases, — particularly at the cardiophrenic angle, — the middle lung field in 29, and the upper lung field in 13. The entire lung field was involved in 5 cases. Patchy areas of infiltration with indistinct borders were considered the most typical picture, but several cases of distinctly lobar consolidation were seen. Accentuation of the lung markings, giving a streaked appearance of the involved area, was more pronounced than it is in most cases of bacterial pneumonia. A few of the x-ray films, taken separately and without regard for follow-up study, could easily have been interpreted as indicating pulmonary tuberculosis. Many cases showed the most extensive changes when the general condition of the patients had been improved for several days.

In addition to providing bed rest, good nursing care and adequate intake of fluids and salt to combat unusual loss from sweating, which was often excessive, the main efforts in treatment were directed toward relief of the most annoying symptoms. Inhalations of steam, expectorants containing iodine, and codeine afforded the best relief from cough, especially in the early stages. Salicylates, with or

without codeine, gave fair relief from headaches. Hot gargles or irrigations of saline or weak perborate solutions were frequently used for sore throats. Two of the 4 patients with sinusitis were successfully treated by the usual simple measures, but the other two required displacement procedures. Administration of increased concentrations of oxygen was rarely necessary; its use was disappointing in the patients who needed it most — namely, those with dyspnea and cyanosis. There appears to be no specific therapy for atypical pneumonia. Favorable reports of the use of x-ray treatment and of blood transfusions from convalescent patients have appeared, but we have had no experience with these measures.

The three fatal cases require special consideration, and are described in the following reports.

CASE 1. C. T. B. (D.H.H. 5587), a 19-year-old college student, entered the infirmary on March 21, 1942, with a 24-hour history of chilliness, cough, sore throat, malaise and discomfort in the midchest anteriorly. He had been dismissed from the infirmary 8 days previously, after a stay of 17 days, having made a good recovery from infectious mononucleosis, which was typical from both clinical and laboratory standpoints. The rest of the history was not remarkable.

Physical examination soon after admission showed few signs in the chest, but x-ray examination of the chest on the day of admission showed irregular mottling in the right base. Dyspnea, although not apparent in the first 3 days, gradually became more distressing until death 10 days after entry. This was associated with cyanosis and was not relieved satisfactorily by an oxygen tent that was used continuously for the last 7 days of the illness.

The white-cell count varied from 6000 to 12,000, with 37 to 85 per cent polymorphonuclear leukocytes. During the last few days the percentage of immature cells increased to 31 per cent. The sputum showed mixtures of organisms but no hemolytic streptococci or typable pneumococci. Two blood cultures showed no growth.

Sulfadiazine given in adequate doses for the first 3 days was ineffective. Two additional x-ray examinations showed increased consolidation in the base of the right lung and a spreading lesion in the left hilar region. Dr. Donald S. King, of Boston, who saw the patient in consultation 2 days before the fatal outcome, agreed with the diagnosis and therapy and suggested that the poor response was possibly due to the blood changes resulting from infectious mononucleosis. Death was preceded for 4 days by an agitated delirium. Permission for autopsy could not be obtained.

CASE 2. E. C. D. (A 27,848), a 79-year-old retired printer, entered the hospital on November 3, 1942, with a 3-day history of cough and chills. He had made a good recovery from pneumonia 8 months previously. Otherwise the past history was irrelevant.

In addition to a clouded mental state and a distended, tympanitic abdomen, examination revealed labored breathing and patchy signs of consolidation in both lungs, confirmed by x-ray examinations. There was no improvement with sulfadiazine. The respirations became more rapid and labored in spite of the use of an oxygen tent, cyanosis appeared and became more marked, and the patient died 6 days after admission.

The white-cell count varied from 6000 to 9000, and a single differential count showed 81 per cent polymorphonuclear leukocytes. A blood culture was sterile, and only untypable pneumococci were present in the sputum.

Autopsy. The main findings were extensive, patchy areas of gray and red consolidation in both lungs, much frothy, gray-red fluid and purulent material exuding from the bronchi, 1000 cc of clear fluid in each pleural cavity, dilatation of the heart and moderate portal cirrhosis of the liver. Microscopically, the lungs showed scattered areas in which the alveoli were filled with pale, pink material; other areas contained

polymorphonuclear leukocytes and large, pigment-filled macrophages. The pathologists considered these findings consistent with virus pneumonia.

CASE 3. H. B. (A 330), a 38-year-old man, was admitted to the hospital on December 22, 1942. He had suffered from asthma for a long time and was an alcohol addict. For 7 days before entry he had complained of chills, malaise, headache, productive cough and dyspnea. Sulfadiazine had been given before admission, without improvement.

Physical examination showed euphoria, dyspnea, rapid respirations, widely scattered rales and signs suggesting consolidation at both bases—confirmed by x-ray examination. The patient's condition deteriorated gradually in spite of oxygen therapy and other supportive measures, and he died 8 days after admission following a 3-day period of coma.

The white-cell count increased from 7000 to 14,000, with 75 to 94 per cent polymorphonuclear leukocytes and 22 per cent immature forms. The sputum showed a mixture of organisms, including untypable pneumococci. No blood culture was done.

Autopsy. There were patchy areas of consolidation in both lungs, much gray-green, tenacious material in the bronchi, enlargement of the hilar lymph nodes and punctate red areas in the white matter of the cerebrum, internal capsule and the middle and superior cerebellar peduncles. Histologically, all regions of the lung revealed marked congestion of the alveolar capillaries. Some alveoli were filled with pink, amorphous material and others had interlacing strands of fibrin. The most characteristic appearance was that of masses of large macrophages filling the alveoli. Areas of necrosis were frequent. In some sections fibroblasts were growing into the alveolar exudate. Other findings were acute hemorrhagic encephalitis and petechial hemorrhages of the kidneys.

SUMMARY

Primary atypical pneumonia is discussed, particularly in the light of experience with 122 closely observed cases in a twenty-six-month period.

Certain points in differential diagnosis are emphasized, with special reference to symptoms, signs, and x-ray findings.

A case with bronchiectasis as a late complication is reported.

The clinical features of 3 fatal cases and the pathologic findings of 2 autopsied cases are described in detail.

DISCUSSION

DR. R. C. BATT, Berlin: I have had 2 cases of atypical pneumonia in the last year, and one of them was mistakenly

diagnosed as tuberculosis, without adequate findings. It is extremely important to take roentgenograms of the chest, but it is also important not to lose track of the clinical picture of the picture. In the case just mentioned there was involvement of the right upper lobe and a suspicion of cavities. It is impossible to distinguish by x-ray examination between atypical pneumonia and tuberculosis, but this differentiation is very important, and Dr. Gundersen has shown how to make it.

I should like to know whether Dr. Gundersen considers night sweats typical of this disease.

DR. R. W. ROBINSON, Laconia: I should like to ask Dr. Gundersen whether he has come across a complication such as we have had in 3 cases that were diagnosed as influenza infection. For some weeks before admission to the hospital, and at that time also, all had symptoms of pleuritic pain. X-ray examination showed what appeared to be massive fluid—in 2 cases on both sides of the chest and in 1 on one side—but tapping failed to produce fluid. Six weeks later in all 3 cases there was evidence of a localized empyema, which was opened. The organism in each case was a staphylococcus. All the patients ran a clinical course that was identical with that of Dr. Gundersen's patients. The blood pictures were also identical; that is, the white-cell count was never above 9500.

I am wondering whether pleuritic infection is a frequent complication of atypical pneumonia.

DR. C. L. SMART, Laconia: What does Dr. Gundersen think of x-ray treatment in this type of pneumonia?

DR. GUNDERSEN: In answer to Dr. Batt's question about night sweats, I have no figures for this series, but I am sure they were extremely frequent, and they are hard to handle. For this reason, many physicians are opposed to using salicylates for this disease, because they simply make the situation worse. Of course, the sweats occurred irregularly in many of these patients, coming both during the day and at night. As shown by one of the clinical charts, the fever is most irregular, dropping at any time of the day or night.

I have come across reports of pleurisy and empyema as a complication of this disease, but have not been much impressed with them, because these complications have always been due to pyogenic invaders that have been considered secondary to the atypical pneumonia. In a recent report of some 700 cases (Owen, C. M. Primary atypical pneumonia: analysis of 738 cases occurring during 1942 at Scott Field, Illinois. *Arch. Int. Med.* 73:217-231, 1944), a small percentage of patients with fluid, mostly sterile, was mentioned.

In answer to Dr. Smart's question about x-ray therapy, he may have in mind Dr. Oppenheimer's experience. I have studied Dr. Oppenheimer's report, and for all I know this may be a valuable method of treatment. We have had no experience with it. Certainly Dr. Oppenheimer's reported results suggest benefit, particularly if x-ray treatment was used in the first week or two weeks, and particularly if very small doses were given. I believe, however, that any form of therapy is extremely difficult to evaluate in a disease of this sort, when one cannot even be sure that he is dealing with a clinical entity. There may be many etiologic factors or agents that are responsible for this picture.

NATIVE MEDICAL PRACTICES IN THE SOUTHWEST PACIFIC

RAYMOND A. DILLON, M.D.*

BOSTON

THE small atolls of the Gilbert and Ellice Islands are practically the only remaining places in the South Seas where the grass skirt and the uncovered breast have not come under the white man's ban. Baths are frequent and the natives are clean. It is refreshing to get away from the usual greasy, dirty, ragged Pacific "Mother Hubbard," with its long sleeves and high neck, so out of place in a steamy climate.

In the Pacific was once the most perfect quarantine against disease ever known — cannibalism. Anyone — disease carrier or not — who strayed to another village was eaten. Social intercourse was reduced to a minimum. If an epidemic broke out in a locality, everyone either died or recovered. The disease did not spread from village to village or island to island as it does today.

In general, there are three types of native treatment: surgery, cautery and massage. Various charms of one kind or another are also extensively used against disease. Conversations with many of the older members of the population indicated that herbal medicines have never been employed, except for the oil of the coconut, which was, and still is, used as a purgative. Its properties are closely similar to those of castor oil. It is obtained by squeezing copra — the dried meat of the ripe coconut.

Every year a great many natives die of pneumonia, owing to the practice of treating a fever by sitting for hours immersed to the neck in cold sea water. In spite of crowded conditions and the centuries-old threat of overpopulation, there is little intestinal disease, owing to the strictly enforced custom of depositing human waste in the sea.

Cauterization of the skin is accomplished by the application of the glowing end of a smouldering torch, made of strips of rags or bark rolled into a cylinder half an inch in diameter. It is applied for about a second. In treating a disorder, the cautery is rarely applied to the actual area of pain, but usually at points above and below it. In abdominal pains, the application is made in a circle, using the umbilicus as a center.

Massage takes the form of pressing, pinching, manipulation, friction and rubbing, but the skill of the natives in this area does not approach that of the Samoans. Massage is principally used to strengthen weakened or stiffened muscles.

Fractures are bathed in hot water and wooden splints are applied. Massage is begun early.

An injured eye is treated with the steam coming from a coconut shell half filled with water into

which heated pebbles have been dropped. Another method is for the doctor to lick the eyeball with the tip of his tongue.

Throughout this part of the world, before the advent of the white man's trading schooner, cutting implements were obtained, of necessity, from whatever materials were locally available. Obsidian, which can be fashioned into knives, axes and arrowheads, is found on some of the volcanic islands. Bamboo has a sufficiently keen edge, when split, to perform such minor operations as circumcision, which is only a dorsal slit. Formerly a sharp-edged shell was often used, but now a favorite instrument is an old safety-razor blade.

On the true coral atolls, which make up the Gilbert and Ellice Islands, bamboo does not grow and there are no volcanic stones, all sand, stone and soil being of coral origin. On some of these islands, it is said that the umbilical cord was usually cut with a sliver of bamboo found on the beach, which had drifted in from the sea. Scrapers and axes are made from fragments of shells or the carapace of turtles, but this kind of material is useless for surgery. For this purpose, the razor-edged teeth of sharks are used. Excellent lancets are made by binding a tooth to a wooden handle 10 inches long and of the diameter of a fountain pen. A number of these teeth lashed to a club make an effective weapon that has been used by these warlike people for centuries.

When a shark is caught, the jaws are removed and dried in the sun. The teeth become loosened when soaked in fresh water, after which they are extracted and kept in a small coconut-fiber bag until needed. The teeth from the upper jaw have a saw-toothed edge and are used in making long incisions, whereas the smooth-edged ones from the lower jaw are used for puncturing the skin, as in bloodletting. The lances are called *ponga*. In use, the lance is held in the left hand so that the point of the tooth is over the spot to be punctured, and the point is driven in by tapping the handle with a mallet ten inches long held in the right hand. Long incisions are made by holding the lance at such an angle that when it is tapped only the front edge of the tooth cuts. The blade is then moved forward and the procedure repeated, the result being a clean incision. This kind of incision is used for removing lipomas, tuberculous lymph nodes, leperous tissue, elephantoid scrotums and the like.

In removing a subcutaneous tumor, such as a lipoma or enlarged tuberculous node of the neck, an assistant, holding a rectangular piece of turtle carapace in each hand, presses downward and inward on either side of the mass so that it is compressed and raised above the surrounding parts. The in

*During 1940 and 1941, Dr. Dillon spent eighteen months with an expedition exploring the lesser-known island groups of the Pacific.

cision is made straight across the top of the tumor in the manner described above, and the distended skin falls apart, exposing the tumor. Owing to compression, there is little bleeding until the pieces of turtle shell are removed, when the assistant attempts to remove the blood by blowing. The tumor is drawn out of the wound by a pearl-shell fishhook or a forklike piece of wood while the surgeon frees it from the underlying tissues. The wound is usually covered with soft strips of beaten coconut husk, bound in place with strips of pandanus leaf, such as are used in making mats. The skin edges are held in apposition by pressure, no sutures being employed.

This method is employed to remove the painful sores of yaws on the soles of the feet, which occur principally in the young. They are completely excised. In the Solomon Islands, this is accomplished by thoroughly scraping out the affected tissue with the fingernail.

In the Southwest Pacific the incidence of yaws is almost 100 per cent, and that of filariasis is extremely high. The crude surgery described above is often used to remove large scrotums found when elephantiasis develops, the hypertrophied tissue being excised after the testicles have been pushed back with the fingertips.

A *ponga* with a long, thick tooth is used for the removal of hydrocele fluid and for bloodletting. In puncturing the scrotum, injury to the testicles is avoided by holding it so that the liquid distends the bottom of the sac, at which point it is incised. In the Tonga Islands, hydrocele is sometimes drained by using a piece of hollow bone from a cooked bird as a cannula.

For bloodletting, the point of the instrument is driven into a distended vein on the anterior surface of the arm. Just what the native indications for venesection are I was unable to determine.

For opening boils or filarial abscesses, a moderately broad tooth with a smooth edge is used. This is done by driving the blade into the abscess with a single sharp blow. At sea, in a small sailing vessel, boils are a frequent affliction. I made use of this rather crude native instrument, after sterilization by boiling, and found it very effective and as painless as any method I know of.

One instrument, with a small, fine-pointed tooth, is used to make small puncture wounds over gum-boils, swollen areas and bruises. In the case of headache or muscle ache, the needlelike point is gradually moved over the whole area of pain while the lance is tapped rapidly and lightly.

In the New Guinea area, I was amazed to hear that the tribal doctor, to cure a headache, shot the patient in the head with a bow and arrow. Investigation revealed that the bow was a miniature one with just enough force to cause a needlelike arrow to draw a tiny drop of blood. A number of these small punctures were made over the aching area.

The end result was essentially the same as in the Gilberts.

As throughout most of the Pacific area, there is no objection to autopsies. The natives often do post-mortem examinations on their close relatives when there is doubt as to the cause of death.

The midwives are respected members of the community and receive payment in the form of food and fine mats for their services. Because of this there is considerable incentive for them to become as skillful as possible. A midwife is visited at about the fifth or sixth month of pregnancy, at which time massage of the abdomen, consisting of a clockwise motion over the uterus, is given twice weekly. This is supposedly done to turn the fetus and assure correct presentation, but there is probably also the intention of producing abortion. This latter is attempted by massage with heavy pressure on the abdomen and by having the patient lie with a heavy stone resting on the abdomen. Another method is to strike the back just below the kidney region with the side of the hand. These methods are quite inefficient, as indicated by the large number of illegitimate children and by the prevalence of widespread infanticide in former times. In some of the islands there were rumors that abortion was produced by potions made from various herbs, but further information could not be obtained. Apparently this is a modern practice, because internal medicine was probably not used in the past.

Superstition plays a large part in the routine of the pregnant woman. She cannot eat while walking on the road for fear the child will beg. She cannot chew the doubled-bodied pandanus fruit for fear of giving birth to twins, and she is not allowed to cut her food with a knife for fear the child will have a harelip.

The midwife is sent for when labor pains begin. The patient takes her place on a bed of mats prepared especially for the occasion. The position adopted during delivery differs among the various localities, the most frequent being the supine one, with the legs bent at the knees. Another is much the same as Sims's position. Often, however, the patient simple squats. The abdomen is massaged, and after the placenta has come away, the cord is tied with a strip of leaf of the pandanus plant. It was formerly severed with the sharp edge of a clam-shell. The orifice of the vagina is smeared with oil and covered with breadfruit leaves, held in place by a T belt of plaited fibers. This pad is removed and a new coating of oil is applied as often as necessary. The placenta is usually buried, with a coconut planted over it.

If the infant does not begin to breathe spontaneously, both the nose and mouth are sucked to remove mucus, and air is blown into the ears and nostrils. Before the cord is cut the placenta is placed in a vessel of hot water and mouthfuls of cold water are squirted over the infant's face.

For the rare cases of puerperal infection, the treatment is massage of the abdomen. This seems to be the usual treatment throughout the Pacific. Once on a visit to lonely Pitcairn, I was told of a patient who had died a few days previously, and was asked how treatment could have been improved. The mother, after giving birth to twins, had had her uterus washed out with an unsterilized fountain syringe from which a large part of the population had recently received enemas. The resulting infection was vigorously treated by massage.

Until the breast supply of milk becomes available, the newborn is given coconut milk, which appears to be adequate. The child is fed at the breast so long as the supply lasts, usually about eighteen months. When the breast becomes unavailable, the child is fed the soft, almost jellylike meat in the interior of the young coconut, beautifully carved spoons of mother-of-pearl being used.

I always enjoyed watching a baby being bathed. This was accomplished very simply by the mother's

holding the infant up in front of her and squirting mouthfuls of water on it.

At Tarawa was the medical center of the Gilberts. Dr. K. R. Steenson had a small hospital consisting of sixteen individual huts. Unassisted, he was trying to look after the health of 45,000 people living on hundreds of tiny atolls spread over a thousand miles of water. He is well trained and well read and a dynamo of energy. Because of the war no new supplies had reached him for a long time and he was using coconut fiber as a suture material. I saw several cases in which this had been used, and the results were excellent. Dr. Steenson is now a prisoner of the Japanese.

I should like in closing to pay tribute to the hard-working physicians of the remote islands of the Pacific. Not once did we run across the "beach-comber doctor" so universal in fiction and the theater. All were able, kind, well trained and doing splendid work against great odds.

A SIMPLIFIED METHOD FOR CULTURING FUNGI FROM THE SCALP*

ERNST BERNHARDT, M.D.†

BOSTON

LIVINGOOD and Pillsbury¹ state, after reviewing the recent American literature, "Ringworm of the scalp cannot be intelligently treated without cultural diagnostic methods." Although it is generally easy to distinguish microsporiasis, trichophytosis and favus from each other by microscopic examination, the statement quoted seems correct, since it may be difficult clinically to distinguish tinea capitis infections with *Trichophyton gypseum* (*mentagrophytes*) from infections with a *Microsporum*. Furthermore, it is impossible to decide clinically whether *Microsporum audouini*, *M. canis* (*lanosum*) or *M. gypseum* (*M. fulvum*) is involved. Cultural diagnostic methods permit the differentiation of the four species mentioned, which is important particularly for *M. canis* and *M. audouini*. These fungi are nearly exclusively the causative agents of tinea capitis in this country. Infections with *M. canis* do not require x-ray treatment, and the search for the ultimate source of infection must be directed to an animal. If *M. audouini* is found to be the causative agent, the patient's classmates and playmates should be examined under a Wood's light; x-ray depilation seems indicated for children too young to expect pubertal changes soon, and not improved after four weeks of less energetic treatment.

Cultural diagnostic methods would probably be used more frequently if they were available at low cost and without special equipment. The present paper reports a method that can be readily performed with little expense at the physician's office and permits the differentiation of the microsporum fungi from each other and from *T. gypseum*.

The most practical formula for the culture medium was found to be as follows:

Rice.....	5 cc.
Water.....	25 cc.
Aqueous 1:10,000 solution of gentian violet†.....	0.8 cc.

The only equipment required consists of a saucepan, 100-cc. or 125-cc. bottles, a 1-cc. pipette or syringe, test tubes, a platinum loop or needle and a microscope.

For the preparation of the medium a test tube marked at the 5-cc. level and another at the 25-cc. level serve as measures. The 1:10,000 gentian-violet solution is made up by adding 1 cc. of a 1 per cent. alcoholic or aqueous solution to 99 cc. of water. The rice is placed in a bottle of 100-cc. capacity and is washed with water, which is changed three times after thorough shaking. The exact amount of water and the gentian-violet solution are then added. The bottles are plugged with nonabsorbent cotton and are heated in boiling water for thirty

*From the Department of Dermatology and Syphilology, Beth Israel Hospital.

†Assistant in dermatology and syphilology, Beth Israel Hospital, graduate assistant in dermatology, Boston City Hospital

†The gentian violet used in these experiments was a brand called Proctanin, manufactured by Merck and Company, Incorporated, Rahway, New Jersey.

cision is made straight across the top of the tumor in the manner described above, and the distended skin falls apart, exposing the tumor. Owing to compression, there is little bleeding until the pieces of turtle shell are removed, when the assistant attempts to remove the blood by blowing. The tumor is drawn out of the wound by a pearl-shell fishhook or a forklike piece of wood while the surgeon frees it from the underlying tissues. The wound is usually covered with soft strips of beaten coconut husk, bound in place with strips of pandanus leaf, such as are used in making mats. The skin edges are held in apposition by pressure, no sutures being employed.

This method is employed to remove the painful sores of yaws on the soles of the feet, which occur principally in the young. They are completely excised. In the Solomon Islands, this is accomplished by thoroughly scraping out the affected tissue with the fingernail.

In the Southwest Pacific the incidence of yaws is almost 100 per cent, and that of filariasis is extremely high. The crude surgery described above is often used to remove large scrotums found when elephantiasis develops, the hypertrophied tissue being excised after the testicles have been pushed back with the fingertips.

A *ponga* with a long, thick tooth is used for the removal of hydrocele fluid and for bloodletting. In puncturing the scrotum, injury to the testicles is avoided by holding it so that the liquid distends the bottom of the sac, at which point it is incised. In the Tonga Islands, hydrocele is sometimes drained by using a piece of hollow bone from a cooked bird as a cannula.

For bloodletting, the point of the instrument is driven into a distended vein on the anterior surface of the arm. Just what the native indications for venesection are I was unable to determine.

For opening boils or filarial abscesses, a moderately broad tooth with a smooth edge is used. This is done by driving the blade into the abscess with a single sharp blow. At sea, in a small sailing vessel, boils are a frequent affliction. I made use of this rather crude native instrument, after sterilization by boiling, and found it very effective and as painless as any method I know of.

One instrument, with a small, fine-pointed tooth, is used to make small puncture wounds over gum-boils, swollen areas and bruises. In the case of headache or muscle ache, the needlelike point is gradually moved over the whole area of pain while the lance is tapped rapidly and lightly.

In the New Guinea area, I was amazed to hear that the tribal doctor, to cure a headache, shot the patient in the head with a bow and arrow. Investigation revealed that the bow was a miniature one with just enough force to cause a needlelike arrow to draw a tiny drop of blood. A number of these small punctures were made over the aching area.

The end result was essentially the same as in the Gilberts.

As throughout most of the Pacific area, there is no objection to autopsies. The natives often do post-mortem examinations on their close relatives when there is doubt as to the cause of death.

The midwives are respected members of the community and receive payment in the form of food and fine mats for their services. Because of this there is considerable incentive for them to become as skillful as possible. A midwife is visited at about the fifth or sixth month of pregnancy, at which time massage of the abdomen, consisting of a clockwise motion over the uterus, is given twice weekly. This is supposedly done to turn the fetus and assure correct presentation, but there is probably also the intention of producing abortion. This latter is attempted by massage with heavy pressure on the abdomen and by having the patient lie with a heavy stone resting on the abdomen. Another method is to strike the back just below the kidney region with the side of the hand. These methods are quite inefficient, as indicated by the large number of illegitimate children and by the prevalence of widespread infanticide in former times. In some of the islands there were rumors that abortion was produced by potions made from various herbs, but further information could not be obtained. Apparently this is a modern practice, because internal medicine was probably not used in the past.

Superstition plays a large part in the routine of the pregnant woman. She cannot eat while walking on the road for fear the child will beg. She cannot chew the doubled-bodied pandanus fruit for fear of giving birth to twins, and she is not allowed to cut her food with a knife for fear the child will have a harelip.

The midwife is sent for when labor pains begin. The patient takes her place on a bed of mats prepared especially for the occasion. The position adopted during delivery differs among the various localities, the most frequent being the supine one, with the legs bent at the knees. Another is much the same as Sims's position. Often, however, the patient simple squats. The abdomen is massaged, and after the placenta has come away, the cord is tied with a strip of leaf of the pandanus plant. It was formerly severed with the sharp edge of a clam-shell. The orifice of the vagina is smeared with oil and covered with breadfruit leaves, held in place by a T belt of plaited fibers. This pad is removed and a new coating of oil is applied as often as necessary. The placenta is usually buried, with a coconut planted over it.

If the infant does not begin to breathe spontaneously, both the nose and mouth are sucked to remove mucus, and air is blown into the ears and nostrils. Before the cord is cut the placenta is placed in a vessel of hot water and mouthfuls of cold water are squirted over the infant's face.

reциably alter the character of the colony or the rate of growth of either fungus. A high percentage of water was used to keep the medium fit for inoculation for more than a month. Ordinary medicine bottles withstood the flaming of their mouths without cracking.

The addition of gentian violet to the medium is necessary to permit simplified sterilization. In a small series of experiments some bottles were found to be contaminated when gentian violet was omitted, but in more than one hundred sets of sterilizations the medium containing gentian violet remained sterile.

The primary colony of *M. canis* appears on gentian-violet rice in a few days. It is covered by aerial hyphae forming a white, cottony growth. The base of the colony soon becomes yellowish. After the colony has grown for a few days, microscopic examination reveals numerous, thick-walled spindle spores (fuseaux) with pointed ends containing when fully developed five to twelve well-defined compartments. The outside of these spores is covered with all excrescences (Fig. 1A).

First cultures of *M. audouini* become visible after two weeks. They lack aerial growth. The colony is characterized by a slightly brownish discoloration spreading at the rate of about 1 cm. a week over the entire surface and throughout the medium. Daylight shows the discoloration earlier than does artificial light. Microscopic examination of smears from the discolored area shows delicate, curved and branched mycelial threads but never spindle spores (Fig. 1B). Comblike formations, quiet mycelia and single chlamydo spores are occasionally found.

Colonies of *M. gypseum* develop a white, cottony aerial growth. The central area of their surface soon turns to light cinnamon. Microscopically numerous spindle spores with four to six compartments are found (Fig. 1D).

The early colonies of *T. gypseum* are covered with white, cottony, felty or powdery growth. After a few days of growth, microscopic examination reveals innumerable spherical or ovoid microconidia, about 2 microns in diameter. During the second week spirals may also be seen (Fig. 1C).

The primary colony of *Achorion schoenleinii* fails to develop aerial mycelium. It is differentiated from that of *M. audouini* by its yellow or orange color and its slower spread, which scarcely exceeds 1 mm. a week (subcultures grow more rapidly). Microscopically, large chlamydo spores are seen in colonies a few days old.

Fourteen strains of *M. canis* were isolated on gentian-violet rice. One isolation failed at the first attempt because of a greenish contaminant, which

also developed on Sabouraud medium. Hair stumps from the same material were covered with 90 per cent alcohol and inoculated after its evaporation; pure cultures then developed on each medium.

Seven strains of *M. audouini* developed on the first attempt on gentian-violet rice. There were enough hair stumps left of most samples to repeat the cultures equally successfully after weeks or even months.

In some cases hair stumps from diagnosed cases were used for culture after the patients had received topical medication. In one of these cases *M. audouini* failed to grow on either gentian-violet rice or Sabouraud medium. Fungicides were supposed to be responsible for this failure. One strain of *M. canis* from a treated patient failed to grow on Sabouraud medium but developed on gentian-violet rice.

The reported experiments show isolation of the fungi usually responsible for tinea capitis to be as successful on gentian-violet rice as on Sabouraud medium. Their features differ widely enough on the former to distinguish them from each other. These statements seem conclusive at least for *M. canis* and *M. audouini*, since fourteen and seven strains of these fungi, respectively, were isolated, numbers not exceeded in the reports of authoritative authors^{2,3} when testing a new or modified culture medium. Other species of *Microsporum* are rarities in this country. If encountered, they may be identified with the help of Conant's² taxonomic study on a polished-rice medium.

The disadvantage of the gentian-violet rice is that Sabouraud medium frequently permits a diagnosis of *M. audouini* at an earlier date. Its advantage lies in its availability without the use of an autoclave, the saving of agar and other ingredients scarcer and more expensive than rice, and its adaptability as an office method for physicians who do not wish to use the services of a mycologist.

SUMMARY

A cultural diagnostic method is described that permits the identification of ringworm fungi of the scalp, particularly species of *Microsporum*, at low cost, without agar and without special apparatus. Fourteen strains of *M. canis* and seven of *M. audouini* were isolated and identified by this method, with checking by cultures on Sabouraud medium.

minutes on three successive days, care being taken that the cotton plugs do not become wet except by steam. On the third day, after the bottles have been cooled to room temperature, they are ready for inoculation.

Fungi are usually isolated by inoculating the surface of a slanted medium at three to five points

The search for a medium was influenced by Conant's² extensive work on rice. This was chosen as a medium because it is available everywhere and does not undergo seasonal changes, as do potatoes. Rice was used instead of starch or flour because these materials are not so easily washed and may be unsuitable for cultures because of adulteration.

FIGURE 1. Fresh Preparations from Colonies on Gentian-Violet Rice Medium (stained with 0.5 per cent cotton blue in lactophenol).

A, *Microsporum canis* (seven-day culture); B, *M. audouini* (fourteen-day culture); C, *Trichophyton gypseum* (eight-day culture); and D, *M. gypseum* (seven-day culture).

1 cm. or more distant from one another. The gentian violet-rice medium should be inoculated only at the center of the surface, using several bottles. The material for culture is best collected under a Wood's light. Small cuts of the intradermal portion of hair stumps are used for the inoculation. The inoculated bottles are kept at room temperature.

bleaching or the addition of preservatives. Numerous samples of rice were tried, including long-grain and partially hulled (brown) rice. Only one kind of rice was encountered on which *M. audouini* did not grow unless the rice was washed. *M. canis* grew on all samples without previous washing. Slight changes in the proportion of water and rice did not

reциably alter the character of the colony or the of growth of either fungus. A high percentage water was used to keep the medium fit for inoculation for more than a month. Ordinary medicine bottles withstood the flaming of their mouths without cracking.

The addition of gentian violet to the medium is necessary to permit simplified sterilization. In a small series of experiments some bottles were found to be contaminated when gentian violet was omitted, in more than one hundred sets of sterilizations the medium containing gentian violet remained sterile.

MEDICAL PROGRESS

INDUSTRIAL HYGIENE IN 1944

IRVING R. TABERSHAW, M.D.,* AND MANFRED BOWDITCH†

BOSTON

AS in all other fields of knowledge, progress and development in industrial hygiene have been profoundly influenced by the war. This is especially true of industrial medicine, since it is second only to military medicine in its contribution to the war effort. While the laboratory continues to add its sum of knowledge, a wealth of clinical data on some of the older obscure and newer specific occupational diseases has been accumulated within the last year.

Our greatly increased industrial populations have benefited from the consultative services of the federal, state and local industrial-hygiene organizations, which now number half a hundred. The states have continued to expand their industrial-hygiene units, and although personnel is still limited, the volume of work has grown enormously. Existing industrial medical departments have expanded and many establishments have initiated this important service. Unions have become interested, and at least one large one retains a medical staff and has written clauses on health and safety into its contracts.¹

REHABILITATION

At the outset of the war, a major problem of industry was to find a proper place for the handicapped worker — those with one eye or with an orthopedic defect, the deaf, the young and the very old, and others who under normal conditions could not compete in the labor market. Industry learned a great deal and did a magnificent job in placing these persons.² The emphasis is now changing, and the knowledge gathered during this period will have to be transposed to the absorption into industry of many veterans with physical and mental handicaps. Industry is well aware of the approaching problem, and its preoccupation with it is indicated by the number of articles published on rehabilitation, especially the plans that various industrial organizations have proposed regarding the reassimilation of its former employees and other veterans into peacetime production. All such programs visualize a medical preplacement examination in which the physician will not only evaluate the worker's disability, but will also be aware of the implications of the job for which the applicant may be fitted. Classification of disabilities and job-analysis codes have been worked out. Use of these

guides will greatly facilitate evaluation of a worker's defects and the physical demands made on him by the job. This involves, of course, an intimate knowledge of the jobs available and a proper scheme for follow-up to determine the success of such placements. Many organizations are interested, the chief one being the Office of Vocational Rehabilitation of the Federal Security Agency, with branches in every state of the Union. These offices are concerned not only with the proper placement of persons, but also with retraining and vocational guidance of those having orthopedic, sensory or mental defects.²⁻⁸

Provision of adequate medical service to the small industrial plant has long been appreciated as a problem of major importance. The community-health nurses have now started in some areas to provide part-time nursing service to the small plant, and it is hoped that they may be trail blazers in the development of a sound program of part-time medical care for the great number of workers employed in such establishments. The important part that the general practitioner plays in the industrial medical scheme has been defined, and the inter-relation between sound industrial practice and good private practice has been stressed. The education of men qualified to specialize in industrial practice is coming to the fore, and numerous schools are developing programs for undergraduate and postgraduate work in the fields that industrial medical practice entails.^{9,10} A fellowship has recently been established in connection with the Industrial Hygiene Foundation at the University of Pittsburgh, and a school of industrial health is being developed at the Wayne University College of Medicine; the latter will confine itself to teaching and research problems.

The public-health aspects of industrial hygiene have continued to receive attention. This is especially true of tuberculosis surveys, which both federal and state agencies are actively promoting among industrial workers.

ALUMINUM THERAPY FOR SILICOSIS

In 1937, Denny, Robson and Irwin¹¹ published some observations on the effect of finely powdered metallic aluminum in the prevention of silicosis. At about the same time, Gardner and his associates¹² at the Saranac Laboratory, working independently and unaware of the work of the Canadian group, had been conducting similar experiments, using one of the hydroxides of aluminum. Since that time a

*Physician, Massachusetts Division of Occupational Hygiene.

†Director, Massachusetts Division of Occupational Hygiene.

iber of experimental and clinical investigations e been in progress, and the concept has been igned from that of using aluminum to prevent osis to its use for the treatment of silicotic pa-ts.

The first problem was to establish the harmless-s of aluminum. Although some doubt had been t on this by German investigators, who described pneumoconiosis due to aluminum,^{12,13} these ob-vations have never been confirmed and it is now-erally accepted that aluminum, at least in the ounts used for such treatment, does not produce rmful effects. A recent report, however, de-scribes attacks of bronchial asthma due to an al-gic sensitivity to aluminum dust.¹⁴ Hannon,¹⁵ ing the powdered metallic aluminum, found that a series of 145 men with silicosis and disability, were improved, 2 made worse, and 6 unimproved. another group with positive x-ray findings but disability, 93 out of 104 improved. Another roup of 185 were treated prophylactically, and at e time of writing had not developed any signs or ymptoms of silicosis. Gardner and his co-workers eated a limited number of cases, using gelatinous lumina, a material that appears to have the ad-vantages of being more stable, as effective and asier to apply. The treatment consists of daily nhalations of freshly powdered metallic aluminum r of the gelatinous alumina. First for five minutes nd ultimately for thirty minutes each day. Be-tween two and three hundred treatments are given, depending on the patient's response.

The work of both groups of investigators has demonstrated that aluminum or alumina, when introduced into the animal body, will prevent silicosis provided the irritant (quartz) and the inhibitor (aluminum) ultimately localize in the same phagocytic cells. Injection of aluminum or alumina prevents further enlargement of fibrous silicotic nodules and causes the resolution of im-mature silicotic tissue. The animals injected with aluminum remain apparently healthy, and sus-ceptibility to tuberculous infection is not increased by the small amounts that are adequate to protect against silica. It seems inevitable that, with the publication of these results of many years of careful investigation, widespread clinical application will occur. It must be remembered, however, that aluminum therapy should be used only under close medical supervision and that the chief method of prevention should still be control of atmospheric dust by engineering methods.¹⁶⁻¹⁸

PNEUMOCONIOSIS

A silica hazard has appeared in the cutting and grinding of quartz crystals for use in radio trans-mission.¹⁹ The manufacture of these crystals is relatively new and undergoing constant change, but the health hazard can be effectively controlled by adequate renewal of the recirculated liquid used

for cooling the diamond-edged saw. Tripoli, which is 98 per cent quartz and produces in experimental animals the typical proliferative silicotic reaction, does not frequently cause human silicosis, although many workers are exposed. This is due to physical properties that prevent its being dispersed in the air as a dust.²⁰

Asbestosis is usually not thought of as a pre-disposing cause of tuberculosis. Two recent re-views describe cases of pulmonary tuberculosis and asbestosis^{21,22}; these findings, however, may be coincidental. Although it is true that the series is limited, the finding of an increasing incidence of pulmonary carcinoma in persons suffering with asbestosis seems too significant to be overlooked.^{23,24} The role of pulmonary allergy in industrial occupa-tions has been examined. Occupational groups most frequently affected by respiratory allergy are labora-tory workers, food handlers, jewelers, cosmeticians, pharmacists, chemists and furriers. Treatment con-sists of removal from the environment, and in some cases, desensitization.^{25,26}

A series of cases of a chronic pneumonitis charac-terized by dyspnea, orthopnea and miliary nodula-tion of the lungs by x-ray study and autopsy is under investigation in Massachusetts. The syndrome has developed in workers employed in a factory making electric lamps. Autopsy of one case brought to light a condition described as "sarcoid," but the usual findings of the Besnier-Boeck's syndrome were not present. The etiologic agent has not as yet been identified, but work continues actively on this phase.

Experiments with silica and feldspar dust on the susceptibility of experimental animals (rats) to lobar pneumonia resulted in lower case rates in the dust-exposed rats than in the controls.²⁷

WELDING

Welding has become the most important and most widely used method of joining metals, and a great number of people are now employed in this occupation. Experience has created a better under-standing of some of the hazards associated with its use, and certain theoretical hazards have been dis-proved by clinical observation. The oft-repeated rumor that welding arcs give off x-rays has no sub-stantiation. Radiant energy in the form of ultra-violet and some infrared rays is the only hazard of this general type. Flash keratoconjunctivitis from the ultraviolet rays constitutes one of the most frequent disabling accidents in welding,^{28,29} but these lesions can be easily prevented by proper safety education. Treatment consists of the use of dark glasses, cold applications to the eyes and local anesthetic, vasoconstrictor and mydriatic lubricating and sedative preparations. Infrared rays are not effective in the management of these lesions.³⁰

MEDICAL PROGRESS

INDUSTRIAL HYGIENE IN 1944

IRVING R. TABERSHAW, M.D.,* AND MANFRED BOWDITCH†

BOSTON

AS in all other fields of knowledge, progress and development in industrial hygiene have been profoundly influenced by the war. This is especially true of industrial medicine, since it is second only to military medicine in its contribution to the war effort. While the laboratory continues to add its sum of knowledge, a wealth of clinical data on some of the older obscure and newer specific occupational diseases has been accumulated within the last year.

Unions have become interested, and at least one large one retains a medical staff and has written clauses on health and safety into its contracts.¹

REHABILITATION

At the outset of the war, a major problem of industry was to find a proper place for the handicapped worker—those with one eye or with an orthopedic defect, the deaf, the young and the very old, and others who under normal conditions could not compete in the labor market. Industry learned a great deal and did a magnificent job in placing these persons.² The emphasis is now changing, and the knowledge gathered during this period will have to be transposed to the absorption into industry of many veterans with physical and mental handicaps. Industry is well aware of the approaching problem, and its preoccupation with it is indicated by the number of articles published on rehabilitation, especially the plans that various industrial organizations have proposed regarding the reabsorption of its former employees and other veterans into peacetime production. All such programs visualize a medical preplacement examination in which the physician will not only evaluate the worker's disability, but will also be aware of the implications of the job for which the applicant may be fitted. Classification of disabilities and job-analysis codes have been worked out. Use of these

guides will greatly facilitate evaluation of a worker's defects and the physical demands made on him by the job. This involves, of course, an intimate knowledge of the jobs available and a proper scheme for follow-up to determine the success of such placements. Many organizations are interested, the chief one being the Office of Vocational Rehabilitation of the Federal Security Agency, with branches in every state of the Union. These offices are concerned not only with the proper placement of persons, but also with retraining and vocational guidance of those having orthopedic, sensory or mental defects.²⁻⁸

Provision of adequate medical service to the small industrial plant has long been appreciated as a problem of major importance. The community-health nurses have now started in some areas to provide part-time nursing service to the small plant, and it is hoped that they may be trail blazers in the development of a sound program of part-time medical care for the great number of workers employed in such establishments. The important part that the general practitioner plays in the industrial medical scheme has been defined, and the inter-relation between sound industrial practice and good private practice has been stressed. The education of men qualified to specialize in industrial practice is coming to the fore, and numerous schools are developing programs for undergraduate and postgraduate work in the fields that industrial medical practice entails.^{9,10} A fellowship has recently been established in connection with the Industrial Hygiene Foundation at the University of Pittsburgh, and a school of industrial health is being developed at the Wayne University College of Medicine; the latter will confine itself to teaching and research problems.

The public-health aspects of industrial hygiene have continued to receive attention. This is especially true of tuberculosis surveys, which both federal and state agencies are actively promoting among industrial workers.

ALUMINUM THERAPY FOR SILICOSIS

In 1937, Denny, Robson and Irwin¹¹ published some observations on the effect of finely powdered metallic aluminum in the prevention of silicosis. At about the same time, Gardner and his associates¹² at the Saranac Laboratory, working independently and unaware of the work of the Canadian group, had been conducting similar experiments, using one of the hydroxides of aluminum. Since that time a

*Physician, Massachusetts Division of Occupational Hygiene.

†Director, Massachusetts Division of Occupational Hygiene.

ber of experimental and clinical investigations have been in progress, and the concept has been changed from that of using aluminum to prevent silicosis to its use for the treatment of silicotic patients.

The first problem was to establish the harmlessness of aluminum. Although some doubt had been cast on this by German investigators, who described pneumoconiosis due to aluminum,^{12,13} these observations have never been confirmed and it is now generally accepted that aluminum, at least in the small amounts used for such treatment, does not produce harmful effects. A recent report, however, describes attacks of bronchial asthma due to an allergic sensitivity to aluminum dust.¹⁴ Hannon,¹⁵ using the powdered metallic aluminum, found that in a series of 143 men with silicosis and disability, 5 were improved, 2 made worse, and 6 unimproved. In another group with positive x-ray findings but no disability, 93 out of 104 improved. Another group of 185 were treated prophylactically, and at the time of writing had not developed any signs or symptoms of silicosis. Gardner and his co-workers treated a limited number of cases, using gelatinous alumina, a material that appears to have the advantages of being more stable, as effective and easier to apply. The treatment consists of daily inhalations of freshly powdered metallic aluminum or of the gelatinous alumina, first for five minutes and ultimately for thirty minutes each day. Between two and three hundred treatments are given, depending on the patient's response.

The work of both groups of investigators has demonstrated that aluminum or alumina, when introduced into the animal body, will prevent silicosis provided the irritant (quartz) and the inhibitor (aluminum) ultimately localize in the same phagocytic cells. Injection of aluminum or alumina prevents further enlargement of fibrous silicotic nodules and causes the resolution of immature silicotic tissue. The animals injected with aluminum remain apparently healthy, and susceptibility to tuberculous infection is not increased by the small amounts that are adequate to protect against silica. It seems inevitable that, with the publication of these results of many years of careful investigation, widespread clinical application will occur. It must be remembered, however, that aluminum therapy should be used only under close medical supervision and that the chief method of prevention should still be control of atmospheric dust by engineering methods.¹⁶⁻¹⁸

PNEUMOCONIOSIS

A silica hazard has appeared in the cutting and grinding of quartz crystals for use in radio transmission.¹⁹ The manufacture of these crystals is relatively new and undergoing constant change, but the health hazard can be effectively controlled by adequate renewal of the recirculated liquid used

for cooling the diamond-edged saw. Tripoli, which is 98 per cent quartz and produces in experimental animals the typical proliferative silicotic reaction, does not frequently cause human silicosis, although many workers are exposed. This is due to physical properties that prevent its being dispersed in the air as a dust.²⁰

Asbestosis is usually not thought of as a predisposing cause of tuberculosis. Two recent reviews describe cases of pulmonary tuberculosis and asbestosis^{21,22}; these findings, however, may be coincidental. Although it is true that the series is limited, the finding of an increasing incidence of pulmonary carcinoma in persons suffering with asbestosis seems too significant to be overlooked.^{23,24} The role of pulmonary allergy in industrial occupations has been examined. Occupational groups most frequently affected by respiratory allergy are laboratory workers, food handlers, jewelers, cosmeticians, pharmacists, chemists and furriers. Treatment consists of removal from the environment, and in some cases, desensitization.^{25,26}

A series of cases of a chronic pneumonitis characterized by dyspnea, orthopnea and miliary nodulation of the lungs by x-ray study and autopsy is under investigation in Massachusetts. The syndrome has developed in workers employed in a factory making electric lamps. Autopsy of one case brought to light a condition described as "sarcoid," but the usual findings of the Besnier-Boeck's syndrome were not present. The etiologic agent has not as yet been identified, but work continues actively on this phase.

Experiments with silica and feldspar dust on the susceptibility of experimental animals (rats) to lobar pneumonia resulted in lower case rates in the dust-exposed rats than in the controls.²⁷

WELDING

Welding has become the most important and most widely used method of joining metals, and a great number of people are now employed in this occupation. Experience has created a better understanding of some of the hazards associated with its use, and certain theoretical hazards have been disproved by clinical observation. The oft-repeated rumor that welding arcs give off x-rays has no substantiation. Radiant energy in the form of ultraviolet and some infrared rays is the only hazard of this general type. Flash keratoconjunctivitis from the ultraviolet rays constitutes one of the most frequent disabling accidents in welding,^{28,29} but these lesions can be easily prevented by proper safety education. Treatment consists of the use of dark glasses, cold applications to the eyes and local anesthetic, vasoconstrictor and mydriatic lubricating and sedative preparations. Infrared rays are not effective in the management of these lesions.³⁰

MEDICAL PROGRESS

INDUSTRIAL HYGIENE IN 1944

IRVING R. TABERSHAW, M.D.,* AND MANFRED BOWDITCH†

BOSTON

AS in all other fields of knowledge, progress and development in industrial hygiene have been profoundly influenced by the war. This is especially true of industrial medicine, since it is second only to military medicine in its contribution to the war effort. While the laboratory continues to add its sum of knowledge, a wealth of clinical data on some of the older obscure and newer specific occupational diseases has been accumulated within the last year.

Our greatly increased industrial populations have benefited from the consultative services of the federal, state and local industrial-hygiene organizations, which now number half a hundred. The states have continued to expand their industrial-hygiene units, and although personnel is still limited, the volume of work has grown enormously. Existing industrial medical departments have expanded and many establishments have initiated this important service. Unions have become interested, and at least one large one retains a medical staff and has written clauses on health and safety into its contracts.¹

REHABILITATION

At the outset of the war, a major problem of industry was to find a proper place for the handicapped worker—those with one eye or with an orthopedic defect, the deaf, the young and the very old, and others who under normal conditions could not compete in the labor market. †Director, Massachusetts Division of Occupational Hygiene.

this reason.⁴⁴ Various compositions of solders containing lead have been fed to rats without producing poisoning; these compounds, nevertheless, may be toxic to human beings.^{45,46} The hazard in shipyards from handling and burning lead-painted materials has been corroborated by a number of observers. After the last war, epidemics of lead poisoning occurred when ships were dismantled or repaired. Non-lead paints and improved methods of handling lead-painted surfaces have now been devised, and a diminution in the number of cases may be expected.^{47,48}

Sodium citrate has been used in the treatment of 5 cases of lead poisoning by Letonoff and Kety,⁴⁹ who report immediate and persistent amelioration of the symptoms. There were no reactions or ill effects from the citrate, and in the majority of cases, appreciable increases in the amounts of urinary and fecal lead occurred during the therapy.

Recognition of the hazard from radium in luminescent dial painting, an operation greatly stimulated by military demands, has led to control measures designed to prevent a recurrence of the anemias and osteosarcomas that cropped up after the last war. Though no state or governmental agency has promulgated a code having the force of law, the employers in some jurisdictions, notably Massachusetts, have co-operated with the industrial-hygiene authorities to bring about admirable working conditions. In an exhaustive article, Evans⁵⁰ has reviewed the problem of radium poisoning and the methods of protection. In many dial-painting plants, as a result of his work, radon determinations of expired air are made at periodic intervals, and from this, the amount of radium stored in the body is determined.^{51,52} A tenth of a microgram is considered the maximum permissible limit, and workers who reach this level of tolerance are transferred to other work or given a vacation. The English do not use breath radon analysis, possibly owing to insufficient technical facilities, but do insist that a three-month vacation from radium work be given each year to people engaged in this occupation.⁵³ So far, no cases of radium poisoning have been reported, and a recent survey of workers exposed from one and a half to four years has revealed no evidence of incipient radium effect.

MISCELLANEOUS CONDITIONS

A vast number of chemicals are used in industry, and knowledge of their toxicity is constantly undergoing revision. Health hazards in the synthetic rubber industry have been summarized.^{54,55} Acrylonitrile, the most toxic substance employed, may enter the body by inhalation or absorption. Styrene, although a dermatitis-producing agent and an irritant of the upper respiratory tract, is not particularly toxic. Butadiene has been found to produce irritation of the upper respiratory tract, but there is no apparent danger in concentrations below the

lower explosive limit. Trinitrotoluene (TNT), since it is being manufactured in such great quantities, still occasionally produces toxemia, but urinary tests have been developed that promise to be of assistance in early determination of hazardous exposure to this substance.^{56,57}

The physiologic principles governing the action of acetone, as well as its toxicity, have been outlined in an extensive article by Haggard and others.⁵⁸ Although acetone, as used industrially, is not extremely toxic, the paper in question reviews the physiologic principles involved in the toxicology of all volatile substances. The amount of glucuronic acid excreted in the urine has been found to be a measure of absorption of certain organic compounds, such as cyclohexanone, aniline and chlorophenol, and may prove to be an early means of detecting absorption and the severity of industrial exposure to some of these compounds.^{59,60} Largent and his associates⁶¹ and others^{62, 63} have studied the effect of fluoride ingestion on experimental animals, and the toxicities of monoalkyl ethylene glycol ethers to dogs and rats have been determined.

The chlorinated hydrocarbons so extensively used as solvents and degreasers still excite great interest, and Hamilton⁶⁴ has reviewed their toxic properties in a recent article. The reports of occupational injuries attributed to these substances have been summarized by Quadland.⁶⁵ The most toxic of these substances is tetrachlorethane, with several reports of fatal poisonings recorded. It may produce acute yellow atrophy, aplastic anemia and respiratory paralysis. In cases of early poisoning, a mononucleosis may be indicative of overexposure.^{66, 67} Other reports stress the action of the chlorinated hydrocarbons as kidney poisons. This is especially true of carbon tetrachloride, which sometimes produces a clinical picture of toxic nephrosis.⁶⁸ Trichlorethylene, used therapeutically by inhalation, has produced ventricular tachycardia in several cases; this phenomenon may account for some of the mysterious deaths reported from industrial exposures to vapors of this and other chlorinated hydrocarbons.⁶⁹

Otologic injuries have recently achieved some prominence, especially in shipyards, where noise is a constant hazard. The threat of deafness to many workers employed in noise-producing operations has been outlined by McCoy⁷⁰ and others.⁷¹ Prevention is difficult, but the problem has as yet received insufficient attention. Audiometer studies of workers before, during and after employment are indicated.

Infectious disease of occupational origin is not frequent, but two types have recently been emphasized. In a study of 24 patients admitted for brucellosis to the Cook County Hospital in Chicago, only one was engaged in an occupation in which exposure might not occur; 17 were employed in packing houses, and 6 others were in contact with domestic animals.⁷² Leptospirosis has long been

The most noteworthy hazard in welding has been recognized to be the pulmonary irritation caused by fumes created by the volatilization of the welded metals. Metal-fume fever has been repeatedly described. There is no clinical evidence that any sequelae dangerous to health develop from this condition. Many workers exposed only to iron oxide have developed a pigmentation of the lung (siderosis), which apparently produces no disability or any increased susceptibility to tuberculosis or other infections, although the presence of iron oxide in the lung has been reported by at least one observer to be responsible for reactivation of tuberculous lesions and for progression of active lesions.³¹ This pigmentation of the lung has been likened to a tattoo of the skin. Many welders, however, do complain of some upper respiratory irritation characterized by a metallic taste, cough and, occasionally, blood-streaked sputum. These symptoms are related to the traumatic effect of the inhaled dense fumes of iron oxide and to the smoke of the organic materials coating the welding rods. This problem of siderosis is coming to the attention of physicians because of the increased amount of welding, and it should be borne in mind that differential diagnosis between this condition, which is entirely harmless, and acute miliary tuberculosis, fungus infections, metastatic carcinoma and silicosis is sometimes extremely difficult and must depend on the history and physical findings of the case.³²

The welding of metals other than steel or iron may produce symptoms. Recent reports, including one of 5 cases, with one death,³³ have re-emphasized the dangers from welding cadmium-plated steel. The mortality rate of metallic cadmium poisoning is estimated at 15 per cent, and the clinical picture is similar to that from exposure to the oxides of nitrogen or phosgene. Symptoms, usually delayed, may start in four to eight hours after exposure, with irritation of the throat, followed by cough and headache, and from twenty to thirty-six hours after exposure the patient may develop symptoms suggestive of pulmonary edema. Volatilization by the electric arc of other metals used as an alloy or surface coating may produce exposure to lead, manganese or chromium, but except for lead, there is little danger of occurrence of a harmful concentration.

Pulmonary disease among welders is not more frequent or severer than in the general population or in those engaged in shipbuilding occupations other than welding and having the same exposure factors.³⁴ There have been, in fact, reports of the healing of tuberculous infiltrates while the worker is still exposed.^{34,35} Technics of providing local exhaust ventilation in welding operations have occupied the engineers, and great strides have been made in this direction. The chief problem of ventilation has been in the holds of ships. Masks with supplied air have also been designed and have some merit.³⁶

DERMATITIS

Dermatitis remains the single most frequent disease directly resulting from occupational exposure. New substances introduced into industry are constantly being identified as being either primary skin irritants or sensitizers. Unpolymerized resins have become increasingly important as plastics in the manufacture of airplane and other military equipment. These vary widely and can be roughly grouped as protein glues, natural-resin glues and synthetic glues. Any of this group may be a dermatitis-producing agent, with the synthetic glues outstandingly the most frequent.³⁷

Another group of substances which has drawn attention is that of the antimildew compounds for textiles. Some of these are phenyl mercuric salts or other organic compounds that produce a sensitization dermatitis. In most cases the use of protective clothing prevents the worker from developing a skin lesion. In addition to the synthetic resins and fabric finishes for waterproofing, flameproofing and mildewproofing, antioxidants used in rubber manufacture may also be responsible for the production of a dermatitis. For instance, the monobenzyl ether of hydroquinone used in this fashion often produces a leukoderma.³⁸

The cutting oils still remain a problem. Sterilization of the oil and the introduction of antiseptics will not prevent a rash; cleanliness and minimal contact with the oil are of first importance in controlling oil folliculitis. Many of these oils have been shown to contain chlorinated compounds and hence may produce a typical chloracne. Occupational acne may also be caused by crude petroleum, coal tar and the chlorinated naphthalenes, diphenyls and benzols. Preventive measures are available, but with the chlorinated naphthalenes, and diphenyls which are used as insulation materials, these have not been entirely efficacious.³⁹⁻⁴¹

The role of patch tests in occupational dermatitis has been reviewed by Downing⁴² and Schwartz.⁴³ The most comprehensive article is by Schwartz, who points out that patch testing with industrial materials demands careful attention and precise knowledge, and even then a whole gamut of errors is possible. A negative result does not rule out the tested substance as a causative agent, since it is impossible to duplicate actual working conditions by this test. Criteria for the diagnosis of occupational dermatoses have been established, however, and the methods of control that have been devised are adequate if applied properly and in time.

LEAD AND RADIUM

Experimental studies in the toxicity of lead have demonstrated that a number of lead-containing substances finding increasing industrial use are soluble in tissue fluids. Lead borosilicates used for ceramics and for glass bushings are potentially toxic

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

CASE 30471

PRESENTATION OF CASE

A forty-one-year-old woman, a millworker, was admitted to the hospital with dyspnea.

The patient was in good health until four months prior to admission, when she developed a cold, followed in a few days by a cough productive of small amounts of whitish sputum. There was no fever or malaise. The cough persisted, but she was able to work. About a month later she suddenly developed sharp inspiratory pain along the right costal border anteriorly and posteriorly. At the same time she noted that she was moderately dyspneic at rest. She continued to work, and her symptoms disappeared after a week. One month later, about six weeks prior to entry, dyspnea recurred and became so severe as to prevent all normal activity. At that time she was examined at a local hospital, a roentgenogram revealing a massive pneumothorax on the right, with basal effusion. The right lung was completely collapsed, and the mediastinum was displaced markedly to the left. From then until admission, she remained dyspneic and was limited to bed and chair activity. Eating aggravated the cough, and on one occasion she claimed to have coughed up about a cupful of "yellowish pus." She was unable to breathe when lying on her left side. She had lost 27 pounds during her illness.

Except for a hysterectomy eleven years previously following attempts at self-abortion, her past history was negative.

Physical examination revealed a sturdy, moderately obese woman propped up in bed, in moderate respiratory distress. The trachea was moderately deviated to the left. The chest showed diminished expansion on the right. The percussion note was about equally resonant on both sides. Tactile fremitus and breath sounds were practically absent on the right, and a few musical rales were audible in the right axilla and over the right base. The apical impulse was felt in the fifth interspace in the anterior axillary line, but there were no auscultatory abnormalities.

*On leave of absence

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 90 diastolic.

Examination of the blood revealed 70 per cent hemoglobin and a white-cell count of 12,200. The urine gave a + test for albumin, and the sediment contained 5 to 10 white cells per high-power field. Sputum culture on two occasions revealed beta-hemolytic streptococci.

Roentgenograms of the chest showed the right lung to be composed almost entirely of large cysts (Fig. 1). The upper lobe appeared destroyed, and numerous smaller cystic structures were present in the middle and lower lobes. The right main bronchus was visualized for a distance of 2 cm. but was not well seen beyond that point; no intrinsic lesion could be demonstrated, however. The heart and mediastinum were displaced to the left, somewhat compressing the left lung. Laminograms of the chest revealed a suggestive but indefinite shadow in the right main bronchus.

On the second hospital day the right chest was decompressed, 750 cc. of air being removed. The patient felt much relieved, but the chest signs remained unchanged. Two attempts at bronchoscopy were unsuccessful.

On the twenty-first hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. RALPH ADAMS†: The initial cough productive of small amounts of whitish sputum, without fever or malaise, indicated an attack of bronchitis. Sharp inspiratory pain a month later was a sign of pleural involvement. Its location along the anterior and posterior chest wall is typical of the referred pain of pleural irritation, it being expressed along the somatic fibers of the posterior and anterior penetrating branches of the intercostal nerves. Dyspnea even at rest implied pulmonary insufficiency, presumably from pneumothorax. The symptoms disappeared as the intrapleural air was absorbed. A pulmonary leak recurred one month later, and dyspnea was severe because of tension pneumothorax and pleural effusion. Roentgenologic examination at a local hospital furnished confirmation. The markedly displaced mediastinum and completely collapsed right lung provided an explanation of the dyspnea.

The patient remained dyspneic even in bed because of limitation of the respiratory reserve by the abnormal intrathoracic pressures. Most patients with a cough find it aggravated by eating. The coughing up of about a cupful of "yellowish pus" probably represented the raising of fluid spilled out of a previously blocked cyst. Her inability to

†Surgeon, Lahey Clinic, Boston

known to be occupational, in that miners and others frequently develop the condition as a result of contact with ground water infected with the urine of diseased rats. Fourteen such cases were recently reported in an Alabama mine,⁷⁸ and there has been an outbreak of the same disease in a New England fishery. Although carrying a grave prognosis, two of the former cases were cured with penicillin.

can be obtained from the Bucky film, namely, suggestion of a lesion in the right main bronchus. The left lung field appears to be normal.

DR. ADAMS: Will you put up the left anterior oblique film?

DR. ROBBINS: In this film the right main bronchus can be seen to this point.

DR. ADAMS: Your interpretation differs from the record.

DR. ROBBINS: It should not, because I gave most of the interpretation.

DR. ADAMS: The record states, "No intrinsic lesion could be demonstrated." Is that still your impression?

DR. ROBBINS: I cannot be positive that there is a lesion there, but I am suspicious because of the Bucky film and because of the fact that one can follow the right main bronchus to a point where it stops abruptly.

DR. ADAMS: Experiences at these exercises heretofore have taught me that the more apparent the diagnosis, the more carefully one should seek the unemphasized morsel of evidence (the "red herring" or, more explicitly, the "hidden slug"). I have therefore looked diligently for clues to some collateral morbid process in this case. The negative evidence is important only in the process of exclusion. The patient did not have hemoptysis, as practically always occurs at some time in some degree with bronchiogenic tumor, whether benign or malignant. By x-ray examination the primary bronchi were found open and clear. One cannot, then, properly retain bronchial adenoma or pulmonary carcinoma for causative consideration. She did not have a chronic cough productive of purulent or foul sputum, and since this is a constant concomitant of bronchopulmonary suppuration, that diagnosis also is untenable. The sputum apparently contained no tubercle bacilli; furthermore, there was no wheeze, and bronchial stricture is the only means by which tuberculosis could have led to the recorded cystic destruction. Tuberculosis is hardly worthy of inclusion in the differential discussion.

I confess, however, that I am still troubled by one point. The left anterior oblique film, taken to demonstrate the bronchi of the right lung in profile view, shows a niche in the lateral wall of the right primary bronchus, beginning 5 mm. below the carina, and itself 7 mm. in length (Fig. 1). Immediately above the niche is a curved cylinder of radiolucence 2 mm. in width and 6 mm. in length, lying in the position that a right-upper-lobe bronchus normally occupies. But it is too small for the right-upper-lobe bronchus, and too large for an artefact. Unfortunately, the laminographer did not record a section film at the proper depth to show the right bronchial tree, and bronchoscopy was not possible. One is again reminded of the frequently essential nature of bronchoscopy in establishing an accurate

pulmonary diagnosis. Notice that the margin of the niche in respect to the primary bronchus is concave, as would occur with fibrosis and scar contraction, rather than convex, as would occur with a propagating tumor. The remnant of the upper-lobe bronchus is so narrow that edema, as from bronchitis, could easily prevent egress of air, and be followed by rupture of the cyst and spontaneous pneumothorax, which would initiate the clinical and physiologic history of this case.

After devoting so much time to the clinical and physiologic features, I shall briefly discuss the anatomic and pathologic features of the disease. Many forms of pulmonary cysts no doubt are acquired, as by parenchymal dilatation from hemorrhagic effusion or distention from infected secretions distal to bronchial obstruction of an inflammatory nature. Cystic bronchiectasis, statistically the most fatal form, is the prime example of this type. Emphysematous blebs lying subpleurally, with a background of asthma or pulmonary fibrosis, comprise a second acquired type. Closely similar are the huge solitary cysts that occur as late complications following the inhalation of a noxious gas. Phosgene poisoning in World War I contributed several cases to this group, one of which I treated surgically only eighteen months ago, twenty-five years after the initial injury. The majority of cysts, however, are believed to be congenital in origin. A lining membrane of ciliated epithelium is generally present, and anthracosis in the residual lung parenchyma is infrequently found, intimating lifelong failure to aerate that portion of lung. The frequency of associated bronchial and vascular abnormalities is high.

Some cysts contain viscid albuminous fluid consisting chiefly of epithelial debris, as well as air; they may empty spontaneously and then refill with air under tension. The patient coughed up a cupful of such material and called it "pus." The postnatal behavior of the congenital type is influenced by the amount and manner of bronchial communication and above all by the time and virulence of complicating infection. The disease is likely to be clinically silent until a check-valve mechanism is established in a communicating bronchus. In this patient it was silent for forty-one years.

I assume that the operation was a pneumonectomy. On the basis of a small experience with this disease, I am willing to predict that the operative and pathological examinations of the specimen showed a pulmonary artery of much smaller diameter and greater thickness of wall than normal, fibrosis and scarring of the right-upper-lobe bronchus with production of a check-valve mechanism, lower-lobe bronchial dilatation of the cystic rather than the truly bronchiectatic type, parenchymal destruction by cysts lined with either ciliated or flattened

breathe when lying on the left side was caused by mediastinal pressure on the already somewhat compressed and only functioning lung. It illustrates the fact that almost every patient with a critical chest condition can breathe better with the afflicted hemithorax lower than the opposite one. She had lost 27 pounds from interference with normal food intake by coughing and from the increased work of dyspneic breathing. The past history seems irrelevant.

Physical examination revealed the findings to be expected in a patient suffering from tension pneumo-

in this hospital, one may properly ask why two attempts at bronchoscopy were unsuccessful. The usual reasons, occasionally encountered, are cervical arthritis, a totally unco-operative patient and a receded lower jaw (best described as a "Burn Gump chin").

The diagnosis of cystic disease of the lung is obvious. The history is classic, a previously healthy patient in early middle age suddenly developing serious symptoms following a minor respiratory infection. The physical signs are those to be anticipated following rupture of one of the cysts into

FIGURE 1 Anteroposterior and Left Anterior Oblique Roentgenograms of Chest.

thorax with mediastinal displacement into the opposite hemithorax.

The data of the clinical chart indicate that she was in cardiac equilibrium at bed-rest conditions and that she was free of major infection.

Laboratory examinations disclosed a mild secondary anemia and leukocytosis, which could be attributed to the diminished food intake, the chronic respiratory illness and the bronchitis. The urinary findings have no discernible significance. Proof of bronchial infection was found in the sputum culture, which on two occasions revealed beta-hemolytic streptococci.

The roentgenograms were typical of so-called "cystic disease of the lung" and failed to establish evidence of any primary bronchial obstruction.

Decompression of the right chest gave relief by removing pressure on the left lung rather than by restoring function in the right lung. With the excellent endoscopy service known to be available

the pleural cavity secondary to a valve-type obstruction of its small bronchial communication by streptococcal bronchitis and associated edema. The case presentation gives a detailed description of cystic disease in the x-ray report, with a directness of terminology that is not designed to confuse one in doubt of the diagnosis.

DR. LAURENCE L. ROBBINS: The heart and mediastinum appear to be displaced a little to the left indicating that the large cystic structures on the right are under tension. In the lateral view we simply obtain more information about the number and size of these cystic cavities that appear to involve the entire right side of the chest. The Buckley film and grid film clearly demonstrate the trachea and right main bronchus. The trachea appears to bifurcate normally, and the right main bronchus can be seen for a short distance and then stops rather abruptly. The laminogram was not entirely satisfactory and does not give any more information

epithelium: the walls were composed predominantly of smooth muscle with scattered foci of mucous glands and a rare group of cartilage cells. This lesion was therefore a true bronchiogenic cyst.

DR. ADAMS: What about the right-upper-lobe bronchus?

DR. CASTLEMAN: I should think that it was compressed by this cystic mass in such a way as to produce the narrowing observed in the film; we have not investigated that point, however. The lung parenchyma, except for being atelectatic, was normal.

DR. ADAMS: Do you think that it was a form of congenital cystic disease?

DR. CASTLEMAN: Yes. The usual theory of the origin of a bronchiogenic cyst is that it is the result of the pinching off of a lung bud during embryonic life. It increases in size so long as there is a communication with a bronchus. This one is the largest that we have ever seen. They are usually located in the upper mediastinum close to the bifurcation of the trachea.

CASE 30472

PRESENTATION OF CASE

A fifty-year-old man, a former credit manager, entered the hospital because of pain in the back.

The patient had been in good health until two months before admission, when he noticed gradual onset of pain low in the back. The pain gradually increased in intensity, was more or less steady and ranged from "dull to very severe." It was aggravated by coughing and sneezing and was worse when he was flat in bed, so that after a night in bed, he found it difficult to move at all. He obtained some relief by standing or walking and by taking aspirin and Empirin. Every two or three days he also noted pain in the right lower quadrant of the abdomen, which was sharp and crampy in character. With the onset of the pain in the back, the patient also developed severe constipation. Once or twice he noticed bright-red blood in the stools, which he attributed to hemorrhoids. There was considerable straining at stool. When severely constipated the abdomen became distended, but he had no nausea or vomiting. The distention and constipation were relieved by cathartics. His appetite, which had always been good, remained unchanged. He had lost 12 pounds in eight months. About four days before entry he developed edema of both ankles, but there was no dyspnea, chest pain, cough or hemoptysis.

One year before entry, repair of a recurrent inguinal hernia and an appendectomy were performed.

Physical examination showed a well-developed, well-nourished man in moderate distress. The left

border of cardiac dullness was 10 cm. to the left of the midline. An apical blowing systolic murmur was heard. The lungs were clear. There was some tenderness to deep palpation in the right lower quadrant. Palpation anywhere in the abdomen caused pain in the back. Along the crest of the right ilium posteriorly there was tenderness to palpation. Rectal examination was negative except for external hemorrhoids. There was pitting edema of the ankles and feet.

The blood pressure was 145 systolic, 90 diastolic. The temperature was 98.6°F., the pulse 90, and the respirations 20.

Examination of the blood showed a red-cell count of 4,250,000, with 12.6 gm. of hemoglobin. The white-cell count was 6800, with 73 per cent neutrophils. The urine was normal. A blood Hinton test was negative. The serum protein was 7.2 gm. per 100 cc. The nonprotein nitrogen was within normal range.

Anteroposterior and lateral films of the lumbar and dorsal spine and plain films of the abdomen and chest were normal. A barium enema was not entirely satisfactory, but appeared to be essentially negative.

On the second hospital day the patient had considerable pain low in the back, and 16 mg. ($\frac{1}{4}$ gr.) of morphine was given. The pain gradually subsided in the next four or five days. During that time he apparently had difficulty with urination. On the sixth hospital day he experienced numbness over the anterior aspects of both thighs and there was diminished sensation to pinprick. The ankle jerks and knee jerks were brisk and equal, and the plantar reflexes were normal. There was no marked atrophy or weakness, but the pain was so great that accurate testing was impossible. Sudden muscular contraction produced acute sharp pain. The upright position seemed to produce steady severe pain low in the back. An intravenous pyelogram showed prompt excretion of the dye by both kidneys, but the pelves and calyces could not be visualized because the patient experienced a severe reaction, the nature of which is not described in the record. On the seventh hospital day an exploratory laparotomy revealed no abnormal findings. Postoperatively the edema disappeared completely.

On the tenth hospital day lumbar puncture between the first and second lumbar vertebrae gave clear yellow fluid that clotted on standing. The initial pressure was 130 mm. of water; jugular compression caused a prompt rise of pressure to 220 mm. and a subsequent fall to 200 mm. This procedure produced considerable pain low in the back and in the abdomen. Ten cubic centimeters of fluid was removed giving a final pressure of 80 mm. The total cell count was 2 per cubic millimeter. The ammonium sulfate ring test was + + + +, and the total protein 1140 mg. per 100 cc.

epithelium and relative absence of carbon pigment.

In conclusion, my diagnosis is congenital cystic disease of the right lung.

DR. BENJAMIN CASTLEMAN: Dr. Drake, will you describe the operation?

DR. EMERSON H. DRAKE: Our preoperative conclusions were similar to those of Dr. Adams. We thought that the lesion in the oblique view might represent a bronchial lesion of some sort and that we might run into a right lung that was completely destroyed because of cystic disease. The patient had been rather unco-operative. She was a thick-

CLINICAL DIAGNOSIS

Congenital cystic disease of lung.

DR. ADAMS'S DIAGNOSIS

Congenital cystic disease of lung.

ANATOMICAL DIAGNOSIS

Bronchiogenic cyst, extrapulmonary.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The specimen we received was a completely collapsed right lung to which was

FIGURE 2. Photograph of Cystic Mass Attached to the Right Lung.

necked, husky individual and it was impossible to pass the bronchoscope on two occasions.

On opening the chest cavity, the cystic mass obviously contained air. It was thick-walled and dense, and the two pleural layers were adherent. The cystic mass was freed with difficulty from the parietal pleura. An area of collapsed lung, which appeared to be middle lobe, was visualized, but the size of the cyst made it practically impossible to expose the hilum clearly. At one point a small tear was made in the cyst wall, following which a small amount of mucoid material exuded. We were unable to separate any normal lung tissue from the cystic mass, and the whole lung was removed en masse.

The postoperative course was uneventful. She has been seen during the past month and is asymptomatic.

attached on its lateral and posterior portions a huge cystic structure that compressed and rotated the lung so that it lay posteriorly and medially in the chest and thus could not be identified during the operation. The mass measured 25 by 15 by 11 cm. and was attached to the surface of the lung in two places — one at the upper lobe and the other over a large area of the lower lobe (Fig. 2). The attachments over the lower lobe were dense and were exceedingly difficult to separate without tearing the lung. No bronchial communication could be demonstrated.

Section of the mass showed that it was composed of one large cavity, comprising the upper half, and a number of small cavities, occupying the lower half. The walls of the spaces were made up of dense fibrous tissue and were heavily trabeculated. Microscopically the cysts were lined by respiratory

short length, in other words, not a lesion that tended upward for any distance. The symptoms had been going on for a relatively short period of time. Although they progressed rapidly I do not believe that that necessarily implies the nature of the lesion. We must consider all the lesions usually seen at this level. Ependymoma is unlikely, because the site was above the lower end of the conus and an ependymoma is rarely seen there; when it does occur, it is intramedullary rather than extramedullary. In view of the relatively rapid progress of the disability and the absence of a history of injury the leading possibilities are meningioma and neurofibroma, in that order, with a ruptured disk a poor third.

DR. AUGUSTUS S. ROSE: This case is a good example of how "red herrings" can interfere with judgment. I saw the patient prior to the abdominal exploration, along with Dr. Richard Miller and Dr. Wyman Richardson. Dr. Lewis has properly evaluated the edema of the legs, which we failed to do. The man had predominantly abdominal symptoms, we thought, with a palpable liver and tenderness of the abdomen, together with edema that was rather more marked than is intimated by the abstract. I thought that there was a retroperitoneal mass, with obstruction of the vena cava. The patient was difficult to examine that an accurate diagnosis was impossible. The pain was excruciating, and although the comment is made that he received 10 mg. of morphine at one time, he actually received as much as 32 mg. two or three times a day. The pain was literally everywhere below his chest, and whereas it was severer in the back, it was widely distributed. I make these statements not only to defend our course but also to emphasize the unusual features of the case. I made the great error of not doing a lumbar puncture, in spite of the negative neurologic examination. We were swayed by abdominal exploration was performed. A lumbar puncture was done after the negative abdominal exploration, and clear-cut evidence of a

dynamic and chemical block was found, so that a diagnosis was possible.

DR. JAMES B. AYER: Why did the edema disappear after the lumbar puncture?

DR. ROSE: We believed that the edema was postural. The patient could not lie down in comfort, having been forced to sit in a semiupright position or to stand for two months. With hospitalization and abdominal surgery he was forced to lie down, which gave the edema an opportunity to subside.

In retrospect it may be of interest that the onset of the man's pain, which we did not determine until after the operation, came on immediately after he tripped in coming out of a streetcar. He missed the curbstone and came down hard on the extended leg. Pain came on instantaneously and was present intermittently until the time of the operation.

DR. LEWIS: The omission of this history of injury may be significant; it might cause a change in the diagnosis.

DR. ROSE: He did not fall. He simply missed the curbstone as he stepped from the car.

CLINICAL DIAGNOSIS

Spinal tumor.

DR. LEWIS'S DIAGNOSIS

Meningioma?

Neurofibroma?

ANATOMICAL DIAGNOSIS

Neurofibroma.

PATHOLOGICAL DISCUSSION

DR. KUBIK: Dr. W. Jason Mixer performed the operation. On removing the laminae of the eleventh and twelfth thoracic vertebrae he came down on a tumor lying beneath the dura and arachnoid membrane. The tumor, a neurofibroma, was 3 cm. long and 1.5 cm. in diameter.

The patient made a good recovery.

After lumbar puncture there was a questionable level of sensory disturbance in the right groin. On the sixteenth hospital day, lipiodol injected at the fourth interspace was arrested between the twelfth dorsal and first lumbar vertebrae (Fig. 1). On the eighteenth hospital day a laminectomy was performed

DIFFERENTIAL DIAGNOSIS

DR. SAMUEL LOWIS: There are several peculiar things in this case. Some of the difficulties even-

FIGURE 1

tually disappeared, but some of them resulted in an operation that apparently yielded no information concerning the basic problem.

We are told that the patient was in good health until two months before admission, but he began to lose weight eight months before admission despite a normal appetite. The pain was of a type frequently seen with an intraspinal lesion in the lumbar area; that is, it was dull to severe, aggravated by coughing and sneezing, and worse when lying flat in bed. It apparently increased markedly during the time in the hospital, although that is not specifically stated; in spite of this pain, neurologic examination was negative. We are told that the patient had marked abdominal symptoms because of which pyelograms and a barium enema were done, with essentially negative results. In spite of this and without any other given information an exploratory laparotomy was performed, with no

abnormal findings. Is a preoperative diagnosis available?

DR. CHARLES S. KUBIK: It was retroperitoneal lymphoma.

DR. LOWIS: One not infrequently sees abdominal symptoms but quite rarely abdominal signs with lumbar, intraspinal, expanding lesions once they have reached the point of compressing the structures within the spinal canal. We are told that pressure on the abdomen caused pain in the back which is a reasonable finding in terms of a lesion that filled the spinal canal: pressure on the abdomen causes an increase in the intraspinal pressure by back pressure on the lumbar veins, and may cause a shift in the position of the tumor in relation to the nerve roots about it or an increase in the pressure of the mass on the nerve roots. We are told that the patient had urinary difficulty while he was in the hospital. This, too, may be considered to have been a sign of an intraspinal lesion, although one cannot be definite because it disappeared before treatment. We are told particularly, and this seems to me to be of interest, that the pain was rather marked, steady and crampy, and worse when he lay flat on his back, and therefore worse in the morning. This is the kind of pain that one sees not uncommonly with intraspinal lesions that have caused a considerable degree of pressure on nerve roots for a long time. Usually when this has happened there are positive neurologic findings, but their absence is not against an intraspinal lesion. We can overlook the edema: not because it is of no importance but because I can see no way to tie it in with the clinical findings in the history.

May we see the x-ray films? There is no question that there was total block. The fluid had a high protein content and clotted; and I think that we can assume there was no recent inflammation because of the low cell count. The dynamics were consistent with block, though we are told nothing about abdominal compression.

DR. LAURENCE L. ROBBINS: In the plain films of the spine I can see nothing of significance, but the lipiodol examination apparently gives the answer. When this was injected into the subarachnoid space through a needle in the third lumbar interspinous space, it was arrested opposite the twelfth thoracic vertebra.

DR. LOWIS: The distance between the pedicles was measured, I assume, and was normal.

DR. ROBBINS: Yes, and there is no apparent erosion of the pedicles.

DR. LOWIS: There is no history of injury; this is of some significance because one rarely sees a ruptured disk at that level and, when one does, there is generally a history of severe trauma to the back, usually direct. It seems to me that with a lesion in that location, which is about at the conus of the cord, and in the absence of signs referable to the cord itself, the lesion must have been

short length, in other words, not a lesion that tended upward for any distance. The symptoms had been going on for a relatively short period of time. Although they progressed rapidly I do not believe that that necessarily implies the nature of the lesion. We must consider all the lesions usually seen at this level. Ependymoma is unlikely, because the site was above the lower end of the conus and an ependymoma is rarely seen there; when it does occur, it is intramedullary rather than extramedullary. In view of the relatively rapid progress of the disability and the absence of a history of injury the leading possibilities are meningioma and neurofibroma, in that order, with a ruptured disk a poor third.

DR. AUGUSTUS S. ROSE: This case is a good example of how "red herrings" can interfere with judgment. The pain was of a type frequently seen with an intraspinal lesion in the lumbar area; that is, it was dull to severe, aggravated by coughing and sneezing, and worse when lying flat in bed. It apparently increased markedly during the time in the hospital, although that is not specifically stated; in spite of this pain, neurologic examination was negative. We are told that the patient had marked abdominal symptoms because of which pyelograms and a barium enema were done, with essentially negative results. In spite of this and without any other given information an exploratory laparotomy was performed, with no

abnormal findings. Is a preoperative diagnosis available?

DR. CHARLES S. KUBIK: It was retroperitoneal lymphoma.

DR. LOWIS: One not infrequently sees abdominal symptoms but quite rarely abdominal signs with lumbar, intraspinal, expanding lesions once they have reached the point of compressing the structures within the spinal canal. We are told that pressure on the abdomen caused pain in the back which is a reasonable finding in terms of a lesion that filled the spinal canal: pressure on the abdomen causes an increase in the intraspinal pressure by back pressure on the lumbar veins, and may cause a shift in the position of the tumor in relation to the nerve roots about it or an increase in the pressure of the mass on the nerve roots. We are told that the patient had urinary difficulty while he was in the hospital. This, too, may be considered to have been a sign of an intraspinal lesion, although one cannot be definite because it disappeared before treatment. We are told particularly, and this seems to me to be of interest, that the pain was rather marked, steady and crampy, and worse when he lay flat on his back, and therefore worse in the morning. This is the kind of pain that one sees not uncommonly with intraspinal lesions that have caused a considerable degree of pressure on nerve roots for a long time. Usually when this has happened there are positive neurologic findings; but their absence is not against an intraspinal lesion. We can overlook the edema: not because it is of no importance but because I can see no way to tie it in with the clinical findings in the history.

May we see the x-ray films? There is no question that there was total block. The fluid had a high protein content and clotted; and I think that we can assume there was no recent inflammation because of the low cell count. The dynamics were consistent with block, though we are told nothing about abdominal compression.

DR. LAURENCE L. ROBBINS: In the plain film of the spine I can see nothing of significance, but the lipiodol examination apparently gives the answer. When this was injected into the subarachnoid space through a needle in the third lumbar interspinous space, it was arrested opposite the twelfth thoracic vertebra.

DR. LOWIS: The distance between the pedicles was measured, I assume, and was normal.

DR. ROBBINS: Yes, and there is no apparent erosion of the pedicles.

DR. LOWIS: There is no history of injury; this is of some significance because one rarely sees a ruptured disk at that level and, when one does, there is generally a history of severe trauma to the back, usually direct. It seems to me that with a lesion in that location, which is about at the conus of the cord, and in the absence of signs referable to the cord itself, the lesion must have been

e unvaccinated.^{3,4} It is also generally agreed at the attacks that occur in vaccinated children e less severe than those in the unvaccinated.^{2,4} In Massachusetts from 1924 to 1943, 58 per cent all the deaths from this disease occurred in the st year of life, and 84 per cent in the first two ars. The protection of infants from exposure to whooping cough continues to be a vitally important ctor in the control of this disease; the vaccine, wever, is usually not effective in the first six onths of life. Furthermore, reactions are likely be severest at this early age.⁵ The first injection ould be given in the seventh month. The best munity is achieved by giving three subcutaneous jections one month apart. The height of im- nity is reached after three or four months. A ngle dose one or two years later to "boost" the munity is a sound practice and should be en- uraged. Since the incubation period of whooping ough is only about ten days, one should not expect y benefit from vaccine administered to a child ter exposure to the disease, much less after the set of symptoms.

Pertussis vaccine may be combined with diphtheria xoid without producing untoward results follow- g injection, but preparations also containing tanus toxoid produce such severe reactions² at, at the moment, they are unsatisfactory.

Cohen and Scadron⁶ injected pregnant women ith *H. pertussis* vaccine with the result that a high iter of immune bodies developed in the mother nd was transmitted to the baby. As pointed out y Lapin, "such antibacterial passive immunity is notoriously short-lived . . . and no clinical evi- ence of protection against exposure has been forth- oming." Therefore, how much actual protection rom such placental transmissions of antibodies ill come from this method remains to be seen.

Hyperimmune serum supplies a certain degree f temporary passive immunity, and because of this s often effective as a prophylactic measure after xposure in the first months of life. Such protection, owever, does not extend beyond fourteen days. This serum is also of value in the early stages of the isease itself. Indeed, in many institutions it has become routine procedure on admission in all cases

of pertussis in which the children are under two years of age.

Besides hyperimmune serum, advances in the treatment of whooping cough include the use of oxygen in cases in which repeated convulsions result from the anoxemia brought about by severe paroxysms.⁷ Needless to say, oxygen will not control the repeated convulsions that are due to cerebral hemorrhage.

In a disease with such wide variations in severity, it is difficult to determine the value of the various agents that have been said to be of benefit. This is proved by the figures compiled by Stimson⁸ at the Willard Parker Hospital, which showed that, with no particular change in therapy during nine years, the mortality from pertussis varied from 8.8 per cent in 1931 to 2.1 per cent in 1939. In Mas- sachusetts, the fatality rate fell rather steadily from 2.4 per cent in 1927 to 0.4 per cent in 1942. It is to be hoped that with intelligent and wide use of a reliable vaccine even better control of whooping cough will be achieved.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

DUDLEY — Oscar A. Dudley, M.D., of Shrewsbury, died October 28. He was in his sixty-first year.

Dr. Dudley received his degree from Tufts College Medical School in 1907. He had been the health officer of the Massachusetts Department of Public Health for the Worcester district for twenty-five years. He was decorated with the Croix de Guerre by the French government for heroism in World War I. Dr. Dudley held a commission in the Massachusetts National Guard of the United States Army for twenty-eight years, retiring in July, 1939, with the rank of colonel. He was a member of the American Medical Association and the Massachusetts Public Health Association.

His widow and two nephews survive.

MORSE — Frank L. Morse, M.D., of Somerville, died November 5. He was in his seventy-fourth year.

Dr. Morse received his degree from Harvard Medical School in 1894. He had been medical inspector in Somerville

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid, for the United States (medical students, \$3.50 per year); Canada, \$7.04 per year (Boston funds); \$8.52 per year for all foreign countries belonging to the Postal Union.

MATERIAL should be received not later than noon on Thursday, two weeks before date of publication.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston 15, Massachusetts.

THANKSGIVING

DESPITE the prospect, at this date, of another winter of war in Europe with the misery and the loss of life that it entails, and of still unnumbered months to come of the struggle in the Pacific, there is yet every reason why we should proclaim and celebrate our accustomed day of thanksgiving.

We can be thankful, despite the grimness of the present and of the immediate future, that we can clearly see the eventual triumph over our enemies. We can be thankful that years of soft living have made no permanent inroads on our national vitality, that our leaders and our youth have measured up to the task that has been set before them. We can be thankful, in a year of stress, when many privileges have been curtailed and many among us have yielded

to the temptation of exercising undue authority, that we have held a national election and have chosen our leaders and our representatives according to the laws expressed in our constitution. We can be thankful that we have retained this freedom of speech and of action when freedoms in other parts of the world have been destroyed or are being restricted and limited by the hard hand of domineering authority. We can be thankful that we have been able to feed ourselves and others, well, if not lavishly. We can be thankful that the medical and surgical care given to our men in service is the best in the world and that those physicians who are left have strength to serve their communities ably and with faith. We can, in short, be thankful that the principle of liberty still prevails and will prevail.

And what can the nation do to show its gratitude for these basic blessings that so set it apart from the rest of the world? It can continue its part as a loyal, hard-working rear echelon to its armies in battle and to its fleets that have at last secured the freedom of the seas. It can work without complaining, endure without breaking, contribute without holding back and, through the Red Cross, give its own blood in safety to make up in part for the blood that has been shed for it in mortal danger.

THE CONTROL OF WHOOPING COUGH

RELIABLE pertussis vaccine has been available in the United States since 1931.¹ Such vaccine consists of whole, killed, Phase I strains of *Haemophilus pertussis*. Extracts of the bacilli have not proved to be effective immunizing agents. In the near future the Massachusetts Department of Public Health expects to supply a vaccine. With this in view, it seems appropriate to clarify what can be expected of this vaccine in the control of whooping cough.

The value of whooping-cough vaccine in the prevention of this disease in nonexposed children is much less than that of vaccination against smallpox. Lapin² has given an excellent summary of the studies on immunization in his recent book. In the presence of definite household exposure one can expect 30 to 36 per cent of the vaccinated children to become infected, compared with 92 per cent of

JUSTICE AND THE FUTURE OF MEDICINE*

WENDELL BERGET†

WASHINGTON, D. C.

I confess that I stand somewhat in awe of my subject. Justice, medicine, the future, are mysteries about which man can know but little. My profession is the law, which aspires to, even though it does not always attain, justice; about it I am humble enough to be very humble in my knowledge. My profession is medicine; about it you are far more conscious than I as to the vistas that have not been reached and the depths that have not been probed. And the future hangs on far too many threads that are alien to your ship and to mine for either of us to boast that he can chart its course. As a layman in respect to medicine, you are wiser than I in regard to law. But the fact that we differ in training and in experience is an asset. It enables us to speak our separate minds, to compare our viewpoints, to sharpen our differences, to move toward a common understanding.

The law is no mean challenge to the human understanding. Yet my admiration goes out to physicians for the greater mystery that they have set themselves to unravel. For a casual nature has spent countless aeons in putting together that bewildering organism we call man, and a process of discovery has used up millenniums in finding out enough about how the trick was done to help man struggle with his ills and aches toward health. It has taken courage, intelligence, a myriad of guinea pigs and sacrifice of a thousand ancient truths to come far as you have on a trail that still leads into the unknown.

For the man of which medicine is mindful is a curious and wonderful thing. A long course of geologic, geologic and biologic events has made of the permutation of things that anatomically is. Nature, a slow and uncertain workman, took a fraction of eternity in which to make tries, beat retreats, blunder along its creative way. It achieved

in man a result that, if nothing to brag about, is at least passable. The chances against his being here at all are as legion to one; the chance of his being exactly what he is — well, write your own odds.

But the biologic process alone did not create man, for every human being has a distinct culture stamped all over him. At work and at play he is beaten on by a continuous stream of stimuli from the human life pulsing about him. In taking care of himself, finding a way of life, begetting posterity, going on a tear, his pursuit of happiness is pent in by the prevailing culture. Man cannot exist apart from the ways and the beliefs of the folk. We are all of us products alike of the earth and of culture, and adjustment to nature and society, always in process yet never completed, is the condition of our life.

Thus the patient—a curious and stubborn bundle of organs and ailments and resistances—presents a series of enigmas that challenge the skills of the doctor. The man on whom all medicine converges is ancient in contrast to the youthful art that serves him. He was established in his anatomic estate and fitted out with his physiologic heritage long before the “physician” was so much as a word. He bears in structure and function, in organ and senses, the impress of all that the life back of him has met in the ages it has passed through. And, to complicate the problem, man is infinitely variable. The mixture of genes, chromosomes and unit characters into fresh combinations in every individual makes each of us a new experiment. In a word, the doctor's challenge is not a standardized man. My hat is off to the man of medicine for the sheer audacity of the task he has undertaken.

From the medicine man of old to the modern clinic is a long way. Again and again mystery after mystery has been probed; again and again the utterly impossible has won acceptance against ancient truth; again and again the reach of medicine has been enlarged. The doctor's craft, with triumph after triumph to its credit, is still on its way, yet it is set within a larger problem of human well-being

*Presented at the fourteenth annual meeting of the American Urological Association, St. Louis, June 21, 1944.
†This address originally appeared in the November, 1944, issue of the *Journal of Urology*, and is reprinted, with minor changes, by permission of the editor, Dr. Hugh H. Young.
†Assistant Attorney General of the United States

from 1901 until his retirement in 1942. He was an intern at Boston City Hospital, where he became assistant resident physician. At the start of World War I, Dr. Morse enlisted and subsequently was assigned to the Surgeon General's Office in Washington. He went overseas as sanitary inspector of the 89th Division and served with the Army of Occupation. On his return to this country, he was commissioned in the Officers' Reserve Corps and held the rank of colonel until retirement in 1935.

His widow and two sisters survive.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

LANDMAN — Elbert A. Landman, M.D., of Plaistow, died October 18. He was in his seventy-seventh year.

Dr. Landman received his degree from Dartmouth Medical School, Hanover, in 1899.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Health Education on the Industrial Front: The 1942 Health Education Conference of the New York Academy of Medicine. 8°, cloth, 63 pp. New York: Columbia University Press, 1943. \$1.25.

This small volume is made up of the papers read before the Health Education Conference of the New York Academy of Medicine in 1942. They are of timely interest because of the vital interrelations of industry, labor, medicine and government. The following topics are discussed by various authorities: the wartime industrialization of the community and its health implications; food and nutrition in the home and in the work place; disease and handicap detection and control in industry; mental problems and morale in industry; and educational methods and control of accidents in industry.

The Four Hundredth Anniversary Celebration of the De Humani Corporis Fabrica of Andreas Vesalius. Publication No. 7, Historical Library, Yale Medical Library. 4°, cloth, 67 pp., illustrated, with frontispiece. New Haven, Connecticut: Historical Library, Yale University School of Medicine, 1943. \$2.50.

This small bound pamphlet is comprised of the various papers read at the celebration of the four-hundredth anniversary of the printing of the famous anatomy of Vesalius. The papers are reprinted from the December, 1943 issue of the *Yale Journal of Biology and Medicine*, and are here brought together in a volume suitable for ready reference.

Army Surgeon. By Genevieve Fox. With illustrations by Forrest Orr. 12°, cloth, 244 pp., illustrated. Boston: Little, Brown and Company, 1944. \$2.00.

In this book for children Miss Fox relates the story of Alexis St. Martin and Dr. William Beaumont. The story begins with the early life of Beaumont and continues through the period when he was studying the action of the gastric juices on his famous patient, Alexis St. Martin, and ends with the story of the travels of Dr. Beaumont and his patient to Washington and other Eastern cities, where he lectured and exhibited his patient. The book is well written in an easy style and should prove interesting to children in the teen age.

Summary of State Legislation Requiring Premarital and Prenatal Examinations for Venereal Diseases, by Aneta E. Bowden, M.A., Ph.D., and George Gould, M.A., LL.B., assistant director, Division of Legal and Protective Services, American Social Hygiene Association. Second edition, revised by George Gould. 8°, paper, 30 pp. New York City: American

Social Hygiene Association, in co-operation with United States Public Health Service, 1944.

Two years having elapsed since the first edition of this pamphlet was published, it is now found necessary to issue a new edition. During this relatively short period four additional states passed premarital examination laws, four states enacted into law bills dealing with prenatal examination and many other states amended existing premarital legislation. Thirty states have laws protecting marriage by requiring examination of both bride and groom by a physician to include a blood test for syphilis, and a like number of states protect babies by requiring the physician to examine the prospective mother for syphilis as early as possible during pregnancy. This summary provides up-to-date information on all state legislation and can serve as a practical guide to all persons concerned. The California premarital law is suggested as a basis in drafting similar laws. Premarital and prenatal charts show the operation of the respective laws in every state. A new table has been added, giving the legal waiting period in relation to marriage licenses. Each state reference has been revised in accordance with information received and approved by the individual state officers. This small pamphlet is a valuable reference text for all libraries and interested persons.

The Medical Clinics of North America. Chronic Diseases (March, 1944). 8°, cloth, 233 pp., illustrated. Philadelphia: W. B. Saunders Company, 1944. \$3.00.

NOTICES

ANNOUNCEMENT

Following discharge from military service Dr. Newman Cohen has resumed the practice of neuropsychiatry at 475 Commonwealth Avenue, Boston, Massachusetts.

NEW ENGLAND PEDIATRIC SOCIETY

There will be a meeting of the New England Pediatric Society on Wednesday, November 29. The clinical presentation will be held at the Amphitheater, Pratt Diagnostic Hospital, and all other events at Longwood Towers, Brookline.

PROGRAM

- 4:00 p.m. Clinical presentation by the staff at the Boston Floating Hospital.
- 6:30 p.m. Refreshments.
- 7:00 p.m. Dinner.
- 8:00 p.m. The Factors Influencing Dental Caries in New England. Dr. Joseph Volker.

Members of the medical profession and students are cordially invited to attend the evening meeting.

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, NOVEMBER 30

- FRIDAY, DECEMBER 1**
 - 10.50 a.m. Virus Diseases Dr. George Morris (Postgraduate clinic in dermatology and syphilis.) Dowling Amphitheater, Boston City Hospital.
- SATURDAY, DECEMBER 2**
 - *10.00 a.m.-12.00 m. Medical staff rounds. Peter Bent Brigham Hospital.
- MONDAY, DECEMBER 4**
 - 12.00 m.-1.00 p.m. Clinicopathological conference. Peter Bent Brigham Hospital.
- TUESDAY, DECEMBER 5**
 - *12.15-1.15 p.m. Clinicoroentgenological conference. Peter Bent Brigham Hospital.
- WEDNESDAY, DECEMBER 6**
 - *12.00 m. Clinicopathological conference. Children's Hospital.

*Open to the medical profession.

(Notices continued on page xv)

arties under the ordinary law of contract. And in days when any old bargain was held valid, yet to discover a case in which a bungling cian was allowed to get off with a plea of *caveat* or.

e law went to lengths unknown elsewhere to certain that the common health was served. spect to the wares of trade the law of single usually holds; a commodity is available to all wish to purchase on exactly the same terms. nsure adequacy of service, a special rule of law decreed for the physician; he was permitted to ge different fees from patients differently ted. The "sliding scale," as much later it came called, served a definite social end. It elevated cine above commerce, broke the pecuniary action between the doctor's service and his rd, and gave legal recognition to the principle persons were to be served according to their y, that charges were to be assessed in terms of y to pay.

ot so long ago, in my official work, the public acter of the doctor's calling was vividly brought . It is a matter of public record, so I might as confess; I was one of the "small group of will-nen" who instituted the antitrust suit of the ed States against the American Medical Asso-on. The occasion, you will recall, was a boycott of the Medical Society of the District of Columbia ertain physicians employed under a group-h plan. The society had expelled one physician, d a second to break his contract and denied ital facilities to their patients. Now, had the been between rival schools of medical practice, a layman, would not have been entitled to an ion. But both group health and the medical ty stood for orthodoxy; there was no difference . Had the question been a choice between two of many ways of organizing medical service, I d in time have arrived at my own answer. But ould have wanted to get all the facts, examine rience critically and think hard and long before ding. But the issue was far simpler; it was ly a question of a fair field and no favors be-n two rival — and it seems to me immature — s for bringing doctors and patients together. he members of the group, the American Medical ociation seemed to be attempting to keep this : of medical care from having an opportunity rove — or to disprove — its case, and they were nced — the courts have now agreed with n — that the tactics were clearly illegal.

s the case went forward, this notion of medicine he instrument of the common health was the ernment's mainstay. Again and again we had sion to recite the public character of the phy-sion's office. There was a time when an associa-on of doctors acted with the delegated authority he state itself. The Royal Society of Physicians l a charter from the English Crown that con-

ferred on it the right to license, to discipline its own members, to search for and to seize illegal drugs and otherwise as a corporate body to secure the common health. When, much later, Congress issued a charter to the Medical Society of the District of Columbia, it described its rights and obligations in words almost identical with the charter of the Royal Society. But it was careful to withhold from the new medical society all economic power over its members. It refused to confer on it authority to fix any schedule of fees for service; and, to clinch the matter, it stated that the privilege accorded was for scientific and educational work and for "no other purposes" whatever.

The same legal recognition of the public interest marked the law that converged on the case. The American Medical Association — or rather, its attorneys — argued at one time that medicine was not a trade; hence doctors, even as officers of an association, could not be guilty of restraint of trade. And at another time they claimed for the American Medical Association the immunities from antitrust that by acts of Congress have been accorded to the labor unions. If, as the *Journal of the American Medical Association* insisted, it was an insult to call medicine a trade, it is a little hard to see how dignity could be restored by calling its association a trade union. The freedom accorded the unions was intended to make possible collective bargaining with their employers, whereas here a collective bargain between physicians and their patients is just the thing the American Medical Association stood against.

But, just to get the record straight, never once in all the proceedings did the Department of Justice call medicine a trade. Instead, it lodged against the American Medical Association the charge of restraint of trade. Now, "restraint of trade," like a hundred glib medical phrases, is a term of art; one can no more than with a bit of medical nomenclature discover its meaning by looking up its verbal parts in the dictionary. And, as irony would have it, it is medicine more largely than any other calling that has given us this rule against restraint of trade. A doctor sells his practice to another doctor. He covenants that for a period of nine years and within a distance of twenty-five miles he will not engage in practice. For a reasonable time, say two years, he endures his idleness. But the itch to be up and at it grows, and sooner or later the old shingle is hung out. Then the other doctor, who has laid out good cash, becomes indignant, demands what he paid for and calls for justice. The doctor who found that it is not healthy to rust has his ready defense. Society needs his services. The contract he made is in restraint of trade, hence it is void as against public policy.

Sometimes the plaintiff wins, more often the defendant does, but always the court pits the common health against private advantage. The phy-

that up to now has hardly been explored. It will not be solved until we learn to make culture in all its color and drama an instrument of health.

Institutions of some sort must be set up to serve each of the great needs of life. A people must be fed, given laws, protected against the weather, held to a moral code, provided with escapes from the dullness of everyday, fitted out with the comforts and frivolities that make life worth living. As we jog down the centuries and over the globe, the ways in which these great tasks get performed present a most kaleidoscopic picture. If the job be to appease the gods, educate the young, ward off plagues, each people has its own way of doing it. Nowhere is there a final answer; there is always bother and striving that it may be better done.

Now, the health of the people is among the mightiest of these great tasks. Yet the problem of the adequacy of medical care is unusually baffling. For it is only the exceptional person who has experienced all the arts — technical, economic, cultural — that converge in it. A beginning of understanding lies in a recognition of a distinction between the technology of medicine and its organization. By technology I mean all those arts — diagnosis, therapeutics, surgery, radiology, dentistry and the like — that constitute the profession of medicine. By organization I mean all the arrangements, social and economic, by which medical service is made available. It is idle to dispute which is the more important, for there must be a medicine to practice, and there must be some sort of arrangements for bringing physician and patient together. It is no veiled mystery to tell which is the more backward. In the advance of the arts of medicine, the medical profession has done a brilliant job. In the face of this advance it is all the more tragic that progress in the organization of medicine has lagged — and, because of this lag, the nation has not had the full benefit of the profession's superlative performance.

For backwardness in organization I am not disposed to pass out blame. But we should be quite frank in looking into reasons. One must be able to state one's problem before he can solve it, and I wonder whether a primary cause of the backwardness is not a failure clearly to put the question. Is not confusion found in attitude, in approach, at the very beginning of inquiry? To be specific, I profess no knowledge of the practice of medicine, and should I attempt to "lay down the law" as to how to treat an ailment you could — and quite properly — laugh me down. Yet as a group physicians have been little exposed to the discipline of the social sciences, and social organization is as intricate and as full of mysteries as is the art of medicine itself. So that when I hear a physician speaking about the organization of medicine in a tone of doctrinaire finality, I cannot fail to remark the contrast with the courageous and humble search for

truth displayed in his own work. And when I hear the question put as a choice between "private practice" and "socialized medicine," I cannot escape noting a confusion and dogmatism strikingly different from the scientific approach. As for the "either . . . or" of private practice and socialized medicine, there is no such question. There are a myriad of schemes under which the doctor and the patient may be brought together — not a choice between just two.

Here, then, is the main reason for the great lag of organization behind art. Organization must be shaped in the full knowledge of the economic and social arts, yet it also must be shaped to the arts of medicine and the distinctive service it renders. Advance, then, depends on a range of understanding that neither you and your kind nor I and my kind alone possess. It demands a co-operation of professions that is not yet a going fact. As now we take counsel together we are not going to clear up the problem. But this is the kind of thing, multiplied a myriad of times over, out of which will some day emerge the answer to the question of justice and the future of medicine.

* * *

Down through the centuries the common law has recognized the maintenance of "the common health" as one of the great tasks of society. In Europe, and in America, there never was such a thing, strictly speaking, as "the private practice of medicine." From the earliest days the common law has made this clear. It is true that from days of old the doctor held no public office, but his service was — as the judges put it — "clothed with a public interest." At a time when any man — butcher, mercer, wheelwright, baker, fishmonger, candlestick maker — was free to enter the trade of his choice, a license was required of the doctor. To secure his right to practice the candidate had to prove his knowledge, his integrity, his skill. The physician was not free to select or to reject patients at will. As one who followed a common calling he held himself out to serve all in need to the limit of his capacity. No inability to pay a valid excuse for the refusal of his service. The law recognized him as a kind of unofficial servant of the community and exempted him from the ordinary rules of the market. It wisely refused to crowd the relation of doctor and patient into the elementary forms of trade. The doctor rendered a service; the patient, if he was able, paid a fee; but the courts refused to regard the matter as a business deal.

On the contrary, the law judged the relation by reference to the norm of common health. It was recognized that the patient, unversed in the mystery, was unable to judge the quality of service. Hence the doctor, in taking a case, assumed a trust unknown in respect to trade at large. The courts steadfastly refused to bring the rights and duties

lety, and it has not yet been shaped to the circumstances of modern life. In the large cities, and in smaller places, there is something of a trend toward fashionable, middle-class or industrial-maker practice. Here obviously the sliding scale no longer operates, for different physicians serve sons in different income groups.

It is far more serious that charges as a whole are out of accord with the ordinary standard of life. As medicine has advanced, its arts have become more intricate. Yet very little attention has been given toward making up-to-date facilities available at prices the common people can afford to pay. On the whole, it is not that physicians are paid too much; the statistics I have seen lead me to believe that remuneration is quite inadequate. It is rather that there is waste, a failure fully to use facilities, a lack in getting the most out of a trained personnel.

The result is a national tragedy. The rich, who do not have to consider price, are often pampered with a medical care that they may not need. Paupers are often indulged with a service that rises far above the ordinary way of life. The great middle class demands charges on the whole quite above its ability to pay. As a result, a great part of the population is forced to reduce its demand for medical service to the very minimum. A great volume of cases reach the doctors in an aggravated condition that in early stages could have been easily handled. A necessary service is often secured at the cost of a heavy debt — a fact that does not make for health. And a far greater part of the people than I like to admit never come to your patients.

Here, then, is the challenge. The arts of medicine have advanced; the importance of medicine has been enhanced; it has become a necessity to the people and an essential in the operation of the industrial system. It has outgrown the organization into which in days of petty trade it was cast. The demand is for a vaster, more comprehensive, more reliable medical service than exists at present. If an instrument of the common health can be provided on terms the people can afford, the people will rejoice. If you do not help them to it, the people will seize on whatever agencies are at hand as a help. For the universal demand that the common health be served cannot much longer be stayed.

* * *

A new medical order is inevitable. Whether we shall cling to the old or create a new is not the question. The swift course of events has decreed that there can be no turning back. The question is whether what sort of medical order it is going to be, and whether it is the best that wisdom and knowledge can contrive. Like every promising venture, it has its hazards. Is it to be shaped by the best understanding that law, medicine, the social studies,

can bring to it, or is it to be constructed by amateurs in ignorance but with good intentions?

I can understand how, in the face of a new venture, you wonder whether change may not fail to constitute progress. I am certain that there will be serious loss if you sit on the side lines and allow whoever may come to power to shape this new medical order.

As medicine gropes for a new organization, we all hear a lot about the doubts and fears of the profession. Many doctors are fearful lest objectives that have been hard won and that they value highly be lost. Many do not see how things that to them are essential can be fitted into a new order. Let us run through a few of the current perplexities.

A great many physicians are justly fearful that the quality of service will be compromised. From the profession I have frequently heard the argument that when the Government undertakes to look after people's health, the service rendered is invariably poor. With this insistence on quality I fully concur. Nor do I dispute the fact that the new venture may provide a service that fails to meet the standards of the profession. But I cannot follow the argument that a causal relation exists between governmental auspices and poor medicine. The truth is that a new system brings medical care to hosts of people who before have had no access to it. For them there can be no falling off in quality; there has been no service to fall off in quality. But under a new system the provision of doctors and facilities almost always falls short of the new and enlarged demand. As a result, doctors with exacting notions discover much with which they can find fault.

But let us be fair and place the blame where it belongs. The shortcomings are not necessarily due to the new system. They are probably caused by a shortage of personnel and equipment with which to work. It is hardly wise to blame untried arrangements when there is a scarcity of doctors, nurses, clinical facilities and drugs. No system can discharge its obligations if it lacks the men and materials with which to carry on.

Much is said, too, about the maintenance of a so-called "personal relation" between doctor and patient. Like the law, medicine is practiced by persons and is practiced on persons. The patient may be served by one or a number of physicians; the contact may endure for a single call, over a stretch of time or for a long period of years. But in the practice of the profession, there is no escape from a personal relation. The law has made this clear beyond a reasonable doubt. Not so long ago a declaratory judgment was sought in the District of Columbia against the Group Health Association. The action was brought in behalf of the Medical Society of the District of Columbia, which argued that a corporation could not legally engage in the practice of medicine. The Court replied that med-

sician's service is of such public importance that he is not allowed by his own will and to his own advantage to swear away his right to practice. We were able to present more than one hundred cases in which the rule against restraint of trade was applied to medicine. The rule emerged, in fact, very largely out of actions of doctor versus doctor.

With the victory of the Government in the Supreme Court the case is now closed. I advert to it only because it has current significance. It is, to borrow a term from your profession, a symptom of a pathologic condition in the organization of medicine. The organization of medicine has not kept up with its technology. The fault is not individual, but institutional. The cleavage is not to be eradicated by invectives, by isolation from modern thought, by clinging stubbornly to that which was once good. It can be resolved only by an escape from folklore, a probing diagnosis, a conquest of prejudice, a drive at the very heart of the malady.

* * *

Let us briefly survey the great trends that converge on medicine, for they decree a revision of means if the great ends of the Hippocratic Oath are to be served.

First, the art of medicine has refused to stand still. The family doctor — with his bedside manner, his nostrums, his ponderous vocabulary to conceal his perplexities, his downright devotion to duty and sacrifice of self — was once the very epitome of the art of healing. He has been succeeded by the general practitioner, who is a focus to a group of specialists, of which there are now more than a score, each with what a lawyer would call its own jurisdiction. The physician's office, filled with gadgets and contraptions, has become a combination of consulting room, laboratory and miniature hospital. A number of separate shops for x-ray examinations, chemical tests and pathological checkups have become necessary adjuncts. Access to a hospital has become a requisite to the individual physician. Consultation with his fellows has grown into an essential of practice. And behind all this is medicine, which, as science and an art, is on the march. Behind medicine stand optics, physics, chemistry, biology, bacteriology. And still medicine continues to capture provinces that until recently lay beyond its frontiers.

Second, the community that the physician must serve has changed with the times. In the good old days the parson, the squire, the doctor, each held sway over his flock. Allegiance to the family doctor was a tie so firmly rooted that it took a crisis to break it. But the world no longer invites so durable, so personal, so exclusive a relation. The machine, the corporation and the pecuniary calculus have made over our work, our lives, our personal relations. Our society has become urban, industrial, gregarious. We have become a new sort

of wanderers, a race of modern nomads operating a material culture.

For most of us a job has come to replace an equivalent in the old homestead. For most of us livings, no longer taken directly from the farm, are paid between the wages we receive and the prices we must pay. As individuals we are as stubborn as ever our ancestors were. But we act far less on our own and far more as managers, agents, employees. Our industry is operated by corporations; our farmers band themselves into co-operatives; our workers skilled and unskilled, gather into unions; even the great mass of our scientists make their discoveries while working for others. In our culture the group has come to be the regular thing.

Against such forces our minds cannot stand firm. Profound changes in habit, interest and value have come in their wake. The standard of living has moved to a place of primacy among our everyday concerns. It makes the costs of medical service an inescapable problem. The care of the sick can no longer be absorbed by the family; it becomes an item of expense in the budget. If it is a wage earner who is ill, there is a double cost: absence from work means loss of earnings, and bills are there to be paid. So medical service becomes a sheer economic necessity, for unless a man's capacity to work is maintained, he ceases to earn. Health thus becomes an aspect of the operation of the national economy.

And within this urban, industrial, wage-earning society, men and women are becoming increasingly conscious of what they want. Our workers demand health as a condition of their livelihoods. They insist on adequate medical service at a price they can afford to pay, and in their newly won self-respect they will refuse all charity.

Third, a changing medicine has not yet been adapted to its new world. The high objectives of the profession endure, for they are eternal, but they must be freshly applied. Our society cannot be served by an instrument designed to fit the family physician into the village community. Neither my time nor your patience will permit a prolonged analysis, yet two or three soundings will reveal the nature and contours of a very insistent problem.

In the not so long ago the old-fashioned doctor could be depended on to administer medicine for the community. He could see to it that needs were met, service was adequate and costs were justly distributed. The physician of today is in no position to discharge this office. His practice comprehends not the whole community, but a mere fraction of it. If he is a specialist, the fraction is highly selective. And the whole body of physicians, each operating by himself, has no collective instrument by which it can apportion the totality of service in accordance with general need. Nor can it any longer take the specific responsibility of graduated charges. The sliding scale survives as a legacy from a simple

ety, and it has not yet been shaped to the circumstances of modern life. In the large cities, and in smaller places, there is something of a trend toward fashionable, middle-class or industrial-like practice. Here obviously the sliding scale no longer operates, for different physicians serve persons in different income groups.

It is far more serious that charges as a whole are out of accord with the ordinary standard of life.

As medicine has advanced, its arts have become more intricate. Yet very little attention has been given toward making up-to-date facilities available at prices the common people can afford to pay. On the whole, it is not that physicians are paid too much; the statistics I have seen lead me to believe that remuneration is quite inadequate. It is rather that there is waste, a failure fully to use facilities, a lack in getting the most out of a trained personnel.

The result is a national tragedy. The rich, who do not have to consider price, are often pampered with a medical care that they may not need. Paupers are often indulged with a service that rises far above the ordinary way of life. The great middle class is charged on the whole quite above its ability to pay. As a result, a great part of the population is forced to reduce its demand for medical service to the minimum. A great volume of cases reach the doctors in an aggravated condition that in early stages could have been easily handled. A necessary service is often secured at the cost of a heavy debt — a fact that does not make for health. And a far greater part of the people than I like to admit never come to your patients.

Here, then, is challenge. The arts of medicine have advanced; the importance of medicine has been enhanced; it has become a necessity to the people and an essential in the operation of the industrial system. It has outgrown the organization into which in days of petty trade it was cast. The demand is for a vaster, more comprehensive, more reliable medical service than exists at present. No instrument of the common health can be provided on terms the people can afford, the people will not pay. If you do not help them to it, the people will seize on whatever agencies are at hand as a help. For the universal demand that the common health be served cannot much longer be stayed.

* * *

A new medical order is inevitable. Whether we all cling to the old or create a new is not the question. The swift course of events has decreed that there can be no turning back. The question is whether what sort of medical order it is going to be, and whether it is the best that wisdom and knowledge can contrive. Like every promising venture, it has its hazards. Is it to be shaped by the best understanding that law, medicine, the social studies,

can bring to it, or is it to be constructed by amateurs in ignorance but with good intentions?

I can understand how, in the face of a new venture, you wonder whether change may not fail to constitute progress. I am certain that there will be serious loss if you sit on the side lines and allow whoever may come to power to shape this new medical order.

As medicine gropes for a new organization, we all hear a lot about the doubts and fears of the profession. Many doctors are fearful lest objectives that have been hard won and that they value highly be lost. Many do not see how things that to them are essential can be fitted into a new order. Let us run through a few of the current perplexities.

A great many physicians are justly fearful that the quality of service will be compromised. From the profession I have frequently heard the argument that when the Government undertakes to look after people's health, the service rendered is invariably poor. With this insistence on quality I fully concur. Nor do I dispute the fact that the new venture may provide a service that fails to meet the standards of the profession. But I cannot follow the argument that a causal relation exists between governmental auspices and poor medicine. The truth is that a new system brings medical care to hosts of people who before have had no access to it. For them there can be no falling off in quality; there has been no service to fall off in quality. But under a new system the provision of doctors and facilities almost always falls short of the new and enlarged demand. As a result, doctors with exacting notions discover much with which they can find fault.

But let us be fair and place the blame where it belongs. The shortcomings are not necessarily due to the new system. They are probably caused by a shortage of personnel and equipment with which to work. It is hardly wise to blame untried arrangements when there is a scarcity of doctors, nurses, clinical facilities and drugs. No system can discharge its obligations if it lacks the men and materials with which to carry on.

Much is said, too, about the maintenance of a so-called "personal relation" between doctor and patient. Like the law, medicine is practiced by persons and is practiced on persons. The patient may be served by one or a number of physicians; the contact may endure for a single call, over a stretch of time or for a long period of years. But in the practice of the profession, there is no escape from a personal relation. The law has made this clear beyond a reasonable doubt. Not so long ago a declaratory judgment was sought in the District of Columbia against the Group Health Association. The action was brought in behalf of the Medical Society of the District of Columbia, which argued that a corporation could not legally engage in the practice of medicine. The Court replied that med-

icine can be practiced only by physicians and that the Group Health Association, a corporation, did no more than furnish the auspices under which physician and patient were brought together. Whatever the character of the organization, the relation is in essence personal.

An oft-repeated variant of the same theme is the insistence on the right of the patient freely to choose his physician. As a patient I am quite willing to have this right qualified for my own good. A well-recognized principle of economics has it that freedom of choice should be limited where the consumer is not a proper judge of the quality of the ware. If there is one field where freedom of choice should be qualified, it is medicine. For medicine is not one thing but many things. Its services are of a highly technical character. If we are downright honest, you and I know that the layman possesses neither the facts about the distinctive competence of particular physicians nor trustworthy norms to guide his judgment. In a matter of medicine, I am not foolish enough to trust my own choice — and a check with some of my lawyer colleagues indicates that they agree with me. I have over the years, through the devious ways by which a layman gets a little practical knowledge, discovered a physician or two whose judgment I have reason to trust. And with me it is their choice, not mine, that goes.

How many patients have walked into your office whose ailments have been aggravated by an amateur's choice of a physician? If for a moment I can be quite rash, I venture to say that in medicine, competence does not wholly accord with ability to attract patients, as in law it does not always rest on ability to attract clients. List, if you will, the six physicians in your city in whom you repose the greatest confidence. Let me, from the records of the Bureau of Internal Revenue, list the six who have the highest incomes. It is dollars to doughnuts that the lists do not match. People go to the Johns Hopkins Hospital or the Mayo Clinic not to be treated by a particular doctor but to secure skillful service. A personal choice, for that matter, can be secured even under state medicine. But far more important to the patient is the assurance of a high standard of competence.

Nor is wide-open freedom fair to the physician. He should on sheer merit advance in his profession, but in all justice his work should be judged, not by the laity, to whom medicine is still a mystery, but by men of his craft, who can distinguish brilliant from routine work. "The free choice of a physician," I fear, has become a shibboleth that will not stand analysis.

And candor compels me to say that I feel much the same about the argument that group practice robs the physician of his incentive. In its usual form it runs that if a man is on his own, he will give his best; if he works for a salary, he will put in his hours and let it go at that. The age-old traditions of your

honorable profession deny the truth of such an argument. Your code of medical ethics has always elevated the relief of suffering above the pursuit of gain. Its purpose has always been to save the physician from avarice, one of the seven deadly sins. It has long been a canon of yours that service is to be given to rich and poor alike, that quality is not to be tempered to the ability of the patient to pay. My limited experience indicates — and a number of colleagues to whom I have put the question concur — that the mightiest urge to which the physician responds is the pride, the drive, the keeping faith with his calling. A doctor cares, and cares mightily, about the respect of his fellows. A friend of mine tells me of his oculist, who insisted he should stop in Baltimore and consult an oculist there. My friend, professing himself satisfied, saw no occasion for the consultation. Finally the oculist said: "Do I have to be brutally frank? I'm damn proud of that operation on your left eye; Doctor — is my old teacher, and I want an excuse for him to take a peek at my work." You know better than I that a conscientious and resourceful physician is not, if he can help it, going to allow a case to lick him. And, if the case is tough and he loses, it hurts.

Now, I do not say that material things are to the doctor of no account. Like the judge, the lawyer, the engineer, the university professor, he has a right to demand advancement, security, an income adequate to his standard of life. For the professional man such things are necessities. Without them the physician is not in a position to give his best.

But such values depend on no single way of organizing medicine. To say that a doctor will give his utmost if he acts as his own business agent, and that his incentive will be stifled if he receives a salary, is not borne out by experience. The time was when the great scientific advance was the work of the solo inventor. Today the most creative of all work — the progress of science and the useful arts — is the product of men on salary. In the large offices the great mass of lawyers now work on salary, and work as hard and as heroically as the youngster who used to flaunt his own shingle in the breeze. It is true that the chance to become a partner is a prod, but I should not rank it overly high, for work equally as good is done by the lawyers in the Government, where no such opportunity exists. In our institutions of higher learning, research as well as teaching falls to salaried employees, and there you will observe an interest, an excitement, a devotion to duty, an urge to be up and doing. And, to return to medicine, how many thousands of our best doctors are today giving their all without stint in the service of the Army and the Navy?

Ambition, security, income, are necessary things. They have in every age and among the most varied conditions of society driven men to accomplishment. If I were a youngster, I should rather leave the series of judgments that shape my career to men

my own profession than attempt to get ahead translating my skills into the art of winning and losing patients. And, most important of all, why, I ask you, that doctors are troubled by this at when university professors, lawyers in public life, officials who make of government a life-style, never even raise the question? And why is that, when the Government of England first undertook to offer medical service, there was quite a chorus that viewed with alarm the loss of income, whereas today such a doubt remains unvoiced? Is it so easy enough to answer the argument that a state will kill the urge to serve; it is hard to understand why the question is ever asked.

It is too late to turn away from that fearful substitution of the state as employer, for I am already disliking it. As for myself, I have no more fear of a venture of the state into medicine than I have of a venture of the state into law. The venture into law is old — judges, public counsel, prosecuting attorneys, are examples. The venture into medicine — pauper and the criminal aside — is new. But the traditions and high standards that have long prevailed in one realm can be established in the other. The Government, in most of its activities, has adhered to a very high standard of professional competence. If for a moment I may be personal, I have experienced the practice of law in a large private New York office and in the Department of Justice. The Government has never imposed on me the restrictions that I have felt to be a burden. If anything, I have enjoyed a greater freedom than I could have had in a private law office. It is true that frequently my own judgment is tempered by the opinions of my colleagues, but usually a "consultation" — as you call it — leads to a sounder decision than any one of us alone would make.

You are right in insisting that high standards of medical care must not be compromised, but standards are a professional matter. Their chief dependence is on adequacy of resources. They are not inherent in any type of organization. Your current efforts, as well as state medicine, have their insidious dangers. And, since comparative merits are at issue, I am not content with any argument that points out the faults of the one without looking at the faults of the other. As it is now practiced, medicine is exposed to the corroding ways of business. Witness the exposure of fee splitting in the City of New York. Under another dispensation it may be exposed to the strange ways of politics. Which is the greater temptation, I am not able to say. But politics is a thing from which no activity of man is free. It can be employed to achieve holy as well as unholy results. And the state is not, as some of our physician friends seem to fear, a ward heeler leading the doctor how to practice.

I am not, mind you, presenting a case for or against the prevailing system, state medicine or any particular medical order. There is, as I said

in the beginning, no such question as "private practice" versus "socialized medicine," for practice is never private and all medicine has a social function. The question you and I face is harder, more intricate, far more detailed, than any such antithesis suggests. First of all, you must ask what you want medicine to do. That is easy: to furnish to the whole population an adequate service of quality on terms it can afford. Next, you must contrive ways and means for seeing to it that the great variety of services we call medicine are called into play to serve the common health. Next, you must set up protections against the hazards that you and I see so clearly. And finally, all these arrangements must be brought together into a going organization. Such a result is not to be attained by an act of faith or a single trial. The conditions of health vary from city to country, from section to section. The needs of the people as locally felt must be met, and this means variety, flexibility and capacity for adaptation. It means, seek — honestly, objectively, courageously and ye shall find; knock at many doors until the right ones shall be opened to you.

* * *

Thus there is no royal road to a modern medical order. And thus the system we seek is no choice between "private practice" and "socialized medicine." For in following his private calling the physician is fulfilling a social service; in medicine, "private" and "social" have always been and always will be associated. And the terms, so frequently set down as opposites, have only the most evasive content. Private practice has no stabilized form; the private practice of the country doctor who rode his nag, did his rounds, was monarch of all he surveyed, is not the private practice of a modern urologist. And socialized medicine embraces systems as distinct as the charity of the medieval church, the Royal College of Physicians, the clinic of a modern university, a bureau of public health and the Russian way. You can no more get anywhere with such terms than you can practice your profession with a general concept of "disease" as your stock in trade.

The question demands, not an easy answer, but painful, constructive, detailed thought. It demands, too, an indulgence in downright trial and error, without which nothing worth while emerges. A few experiments — far fewer than the length and breadth and depth of the subject demand — have been blazing fresh trails. An increasing number of physicians have enjoyed practice on their own and on salary and are prepared, from experience rather than in speculative terms, to assess debits and credits. In my pocket I have a letter from one such physician who sets down an illuminating comparison by no means to the disadvantage of salaried work.

And, last but most important of all, the war has given a quick step to a trend long in the making.

A host of physicians now in service are conscious of the shortcomings of "military medicine" and have scores of suggestions concerning how it can be improved, but they have become aware of the tremendous possibilities that inhere in a medicine directly organized to perform its function. And millions of soldiers, returned from the front, are going to demand for themselves and for their families the instruments of health to which they are entitled.

The course of events moves fast, and to me a new medical order seems inevitable. My fear is not that we shall not get it—an awakened public, sparked by our veterans, will see to that. My fear is that we shall not bring to its creation all the knowledge, wisdom, understanding we possess. A reference to the Wagner-Murray-Dingell Bill will make my point. About its intent and objectives there can be for me no dispute. Its detail of provisions, however, may or may not fall short of its purpose—I do not know. On ways and means I am open to argument in behalf of something that is better. In respect to the necessity of distributing the cost of protection against ills I am wholly convinced, and I think the American people is adamant.

The medical order that our stalwarts defend has already ceased to exist. A new medical order will come to be even if we do not will it—even, in fact, if we stubbornly resist it. For the medical order, like other institutions, cannot insulate itself against the impinging culture. It must make its response to the great pulsing tides that everywhere else enter our national life. The wiser physicians know that sheer opposition is not going to hold back the tide. They are putting forward—it seems to me a little timidly—proposals of their own. The other day the medical society right here in St. Louis voted approval of a plan for prepaid medical care, and the papers stated that a minority of doctors thought it did not go far enough. Timidity must be replaced by high resolve, and I am afraid that a very old adage that goes back at least as far as ancient Egypt applies here: "If you can't stop a movement, join it."

And, quite seriously, the doctors' joining is essential to the movement's salvation. The organization of medicine is an affair of a couple of shops. It is a job for the craftsman in social order, but it must be shaped to the very life of the medical service it has to offer. If doctors oppose, or stand on the side lines, the layman will create a medical order that may prove to be indifferent or even blind to the values doctors prize most. If the doctors assume a role in creation, they can see to it that no compromise is made with the standards of the profession.

The problem thus becomes one of creation. In respect to a long detail of questions—the selection of personnel, the standards of care, the carrying of risks, the methods of payment, the ways of remuneration—a score of ways are open. The form of organization may follow an agency of state,

the university pattern, the hospital setup or a combination of devices derived from all these. The government may dominate the system, become one of a number of parties to its management or be excluded from it altogether. The venture may fall into the legal form of a public-health authority, nonprofit-making corporation, a series of independent or interlocking corporations, a group of consumers co-operative, a mutual association of the profession and the laity or still something else. Its direction may be lodged with a tripartite board representing the government, the public and the profession, or the public and the profession, free from governmental interference, may assume joint responsibility. It may or may not be state medicine; it cannot escape being social medicine.

It is man for whom medicine exists. Its function must be to keep a whole people in health. The doctor must be the focus, but on his office a host of unlike services must converge. He must not stop with asking, "Of what is this man ill and what can I do about it?" He must also inquire, "Why and how did this man become ill in the way he did?" The quest leads beyond cure to all the conditions on which personal well-being depends. For food, clothing, housing, recreation, family, occupation, social life, are all terms in the equation of health. Nor must man's habitat be forgotten, for adaptation is the requisite of the life process. Many arts must converge into the new medicine; prevention, sanitation, the public health, must become a part of it. At its hub must stand the doctor; it is he who must direct this vast apparatus of skills, specialized personnel, facilities to the service of the human being. The medical order that I suggest—and that which the American people are going to have—will be vaster and mightier than anything we now know.

Such a medical order, it seems to me, should be hailed enthusiastically by the physician. In respect to professional matters his word will go. His opportunities for service will be greatly enlarged. He will have access to facilities that only the exceptional physician can now afford. A shift in work now and then will keep him alive in his profession. He can occasionally get away for further training. And above all he ought to be better able to turn his clinical work to permanent account.

In an abstract way I recognize the values of ivory-tower research. But after all, the heat of the daily round has its own contribution to make. In the last five years Antitrust Division of the Department of Justice has perhaps done more to blaze a path for the law than has any law-college faculty in the land. The result has not been due to any unusual ability of the men in this division; they have simply been on the firing line and have had an opportunity to turn their clinical work to account. To me it seems that one of the great shortcomings of the prevailing medical system is that the practitioner is kept so busy with his patients that he

not translate his work into medical discovery. Thus, in the end, I return to my beginning. I can find you no ready-made medical order on a silver platter. If I could, it would do you no good. I can only suggest to you, whose minds have long been busied with the subject, some reflections of a man of another profession. And I am positive that a service adequate to the times cannot be brought into being without the doctor's creative participation. As doctors and patients we face a crisis, and my appeal is to the ancient wisdom of the profession. The ends of medicine remain un-

changed; ways and means must be found to adapt its practice to the conditions of present-day society. A new organization must be created that an ancient mission be not lost, that once again medicine shall be available to all in need and that charges shall be graduated in accordance with ability to pay.

An instrument of the common health, such as never before has been offered to a people, is within our reach. This is no time for petty doubts and timid moves. In the face of a national challenge we must — as one of our great jurists said of the law — let our minds be bold.

A UROLOGIST LOOKS AT CHANGING TRENDS IN MEDICAL PRACTICE*

HERMAN L. KRETSCHMER, M.D.†

CHICAGO

WHEN your president invited me to take part in your program and suggested that I talk on this subject, I wondered what he had in mind. Does the urologist who looks through the cystoscope have a point of view different from that of any other practitioner of medicine? I believe that he should not have. After all, these social trends are of vital interest and importance to every physician in this country, be he general practitioner, specialist, research worker or teacher.

"Public health is the musical instrument easiest for the welfare worker to play, and the softest chord is the venereal problem. They not only are able to stir the sympathies of the public, but also can arouse it to supporting the movement through fear of infection." Thus spoke Dr. James A. Gardner in his chairman's address before the Section of Urology at the seventy-third annual session of the American Medical Association held in St. Louis just twenty-two years ago. He was one of the first among our members to interest himself in the early manifestations of these beginning social trends.

It is interesting to reflect that at this annual session of the American Urological Association in St. Louis, a part of the program is being devoted to a consideration of social trends from the urologist's point of view. Unfortunately, many specialists have been indifferent to impending social trends. Their aloofness to the many problems of medicine and their lack of interest in the work of their county and state medical societies and in the activities of the American Medical Association are difficult to understand. This is not to say that they have not been interested in their respective special societies, both local and national. The specialist and his special society have

done much toward improving his type of practice and increasing the scope of knowledge along his own line, and have contributed to the training of future specialists and to the rendering of better medical care to the people of this country.

No one will say that this great organization has not met all its obligations in the fullest possible manner, and no one will question the statement that nowhere in the world is urology on so high a plane as it is in this country. Nor will he deny the statement that the people of the United States receive the best urologic care that it is possible to obtain — and this under the present system of practice, without regimentation and socialization. I should, however, like to have each member of this association ask himself these questions: How many times have I attended my county medical society meetings in the last five years? How many meetings of my state and the national association have I attended? What have been my contributions to the work of the American Medical Association and its component societies, besides the presentation of scientific papers?

I am reminded of Dr. Frank Billings's statement made to me in Dallas at the meeting of the American Medical Association in 1926. He told me that he had been a member of the association for forty-five years and had attended forty-four annual sessions. This is an example to be followed by every physician in this country.

I should like to point with pardonable pride to the activities of some of our colleagues in the House of Delegates of the American Medical Association. Although I cannot mention all of them, I should like to mention some of the old wheel horses who have taken an active part in this representative body: Abell, Bandler, Braasch, Cameron, Crockett, Hamer, Low, Parke, Sargent, Smith, the late Terry Townsend and others. In my travels throughout

*Presented at the fourteenth annual meeting of the American Urological Association, St. Louis, June 21, 1944.
This address originally appeared in the November, 1944, issue of the *Journal of Urology* and is reprinted, with minor changes, by permission of the editor, Dr. Hugh H. Young.

†President, American Medical Association.

the country I am pleased to see more and more urologists taking an active part in their county and state societies.

Unfortunately, in this country there is a fetish for passing laws. People seem to think that by simply passing a law all will be well. And they never seem to learn. Note the miserable failure to regiment the drinking lives of the people represented by the Volstead Act. No disease is cured by the passing of a law. Diseases are cured and eradicated by research, medical education and treatment, and not by regimentation. All the laws on the statute books failed to eradicate venereal diseases, but now, as you know, effective drugs are available. I recently heard Admiral McIntire state that the venereal diseases are no longer a problem in the Navy. When, as a result of medical education and research, specific remedies have been discovered and their use by physicians has been established, and when their use does not entail a protracted period of treatment, the co-operation of the patient is readily obtained and the results are almost miraculous.

The regimentation of the people and the physicians has never solved any medical problem. Unfortunately, regimentation only makes matters worse. The various attempts to regiment the medical profession are only a steppingstone in the regimentation of the entire country. Many citizens are now keenly aware of the dangers that will follow such a procedure if applied to the medical profession. Once the medical profession has been regimented, the other professions, as well as commerce, industry, newspapers, communications and other activities, may share a similar fate. Note, if you will, the detailed study given to the Wagner-Murray-Dingell Bill by the American Bar Association.

I do not need to call your attention to the fact that under regimentation medical education and research always suffer, that the quality of medical service to the patient deteriorates and that the cost of the service always goes up owing to an ever-increasing bureaucracy. Some years ago from 51 to 53 per cent of the payments into the *Kranken Kassen* in Germany went for administration and the remainder for all phases of medical care.

Under the present system of practice in the United States the span of life has been increased to sixty-five years; maternal deaths have reached an all-time low despite the fact that over 3,000,000 babies were born last year and that over 58,000 physicians were in the armed forces. Infant mortality was never so low. Diphtheria, typhoid fever and other acute infections are practically nonexistent. Tuberculosis, which has always shown an increase in

every war and after it, has also reached an all-time low. Surely the physicians of this country can be proud of their achievement. It behooves the people to stop, look and listen before they abandon the type of practice that has given them the best medical care possible. Do the "do-gooders" believe that they can improve on the results?

There are isolated areas in this country in which there is need for the extension of medical services, and the medical profession has always been and is now ready to improve such situations. These needs are purely local and can be taken care of on a local basis. Because of these local problems, which can be corrected, there is no justification for abandoning completely the finest medical service in the world.

It is incumbent on every physician to acquaint his patients with the dangers of the regimentation of medical practice. Every physician must devote a certain amount of time every day to informing his patients just what this means in the way of deterioration in the quality of medical care, the limitation of his choice of physician and the increased cost in the form of increased taxes. I believe that once the patient has been educated so that he understands the implications, he will be loath to give up the best medical service that any nation has ever enjoyed.

The medical profession has never been static. It is keenly aware of the importance of increasing the distribution of good medical service to all the people. In order to study this problem, the House of Delegates recently established the Council on Medical Service and Public Relations to study and analyze the various plans that are now in operation and to make available the highest quality of medical care to all the people. Many of you no doubt are familiar with these various plans, and I need not discuss them with you. Not only is the medical profession interested in this subject, but industry and the insurance companies have given this subject much study and consideration.

I believe that it would be most fitting to express a word of greeting in the form of a message to the members of this society who are now in the armed forces. From the letters of a good many who have written to me, they are wondering what kind of world they are coming back to. It was the impression of the 58,000 doctors who went into the armed forces that they were fighting to free the world of regimentation, in other words, to free the world of dictators and to preserve the American way of life.

The question of regimentation of the medical profession and the patient is one that concerns every physician as well as every citizen of this country.

MEDICAL PROGRESS

CARDIOLOGY: THE NORMAL HEART IN OLD AGE*

A. STONE FREEDBERG, M.D.,† AND HERBERT D. LEWIS, M.D.‡

BOSTON

OR some time the aging of the population has been a matter of concern to many. In 1940 approximately 9,000,000 persons, or 7 per cent of population, were sixty-five years of age or over,¹ whereas a study of the trends indicates that in 1980 approximately 22,000,000, or 14 per cent of the anticipated population will be sixty-five or more years of age. This proportion will be reached earlier in some countries, owing to the excess of young manhood in the present war. It is of importance that life expectancy, for the increasing number of persons reaching old age has increased since 1900 (Table 1). Thus, al-

concerning which changes constitute disease and which are those of normal senescence. It is the purpose of this review to summarize the accumulated knowledge bearing on the normal heart in the aged.

ANATOMY

Heart weight. The absolute weight of the heart is said to diminish with age,²⁵ although the ratio of heart weight to body weight increases, according to Muller²⁶ and Gray.²⁷ Other authors, including Sagebiel,²⁸ point out, however, that atrophy does not occur. Rosahn,²⁹ in a study of 187 men with normal hearts at autopsy, found a significant correlation between age, body weight and heart weight. He derived the formula: age (in years) plus 3 times the body weight (in kilograms) plus 100 equals the heart weight. He concluded that a diagnosis of cardiac hypertrophy was justified when the observed heart weight exceeded by more than 77 gm. (approximately 20 per cent of the mean weight for the entire group) the estimated heart weight. Willius and Smith,³⁰ using a height-body weight method for estimating the normal, found approximately one third of a group of 376 patients seventy to ninety-nine years old to possess hearts with normal weights. In the remainder the excess cardiac weight could be explained as consequent to disease processes, such as hypertension, aortic stenosis, adherent pericarditis and myocardial infarction. It should be pointed out that their upper limit of normal weight is low (294 gm. for males, and 250 gm. for females).³¹ It is apparent that there are as yet too few data concerning normal heart weight in the older age groups to permit a conclusion concerning the occurrence of hypertrophy as part of the aging process unrelated to disease.

Gross changes with age. The pericardium tends to become opaque, particularly over the surface of the base of the right ventricle. The apical portion of the left ventricle is said to decrease in size.³² Subpericardial fat tends to increase along the grooves of the coronary vessels, especially in the auriculo-ventricular groove at the base of the right auricle. The valves become more rigid; calcium may be deposited in the mitral and the aortic ring, with calcification of the annulus fibrosis. The sinuses of Valsalva become deeper. Karsner³³ has pointed out that the latter changes may be due to earlier inflammatory disease, with a loss of its identifying

TABLE 1. *Expectation of Life for White Males in the United States (adapted from Dublin²).*

AGE	EXPECTATION OF LIFE			
	AT BIRTH	AT AGE 50	AT AGE 60	AT AGE 70
35	37	37	37	37
45	48.25	20.76	14.35	9.05
55	62.60	21.08	14.36	9.05

though more men and women in this country are living longer, they succumb to invalidism² and die at rates that have been unaffected by general medical progress.

Although the general social aspects of this situation^{3,4} need not be discussed here, it is apparent that methods of prolonging the period of productivity of the aging population are becoming increasingly important. This involves further studies of disease in the aged, in order that preventive medicine⁵ and active therapeutics may be applied. Studies related to old age have been recently undertaken on a large scale,^{6,7} and books,⁸⁻¹³ a journal¹⁴ and symposiums¹⁵⁻¹⁸ devoted to gerontology and geriatrics have appeared.

It has long been known that death from gradual decay is extremely rare and may indeed be nonexistent.¹⁹⁻²¹ Diseases of the cardiovascular system constitute the main cause of death in the aging. Statistical statistics indicate that heart disease is responsible for 25 to 50 per cent of all deaths,²¹⁻²³ and autopsy data are in agreement.²⁴ Many excellent contributions to knowledge of the heart in old age have been made in the past few years, but a basic difficulty in most studies of this sort is the decision

*From the Medical Service and the Medical Research Laboratories, Beth Israel Hospital, and the Department of Medicine, Harvard Medical School.

features. Willius and Smith³⁰ found 93 per cent of hearts from 381 persons aged seventy or more to present varying degrees of valvular sclerosis, so that these changes should be considered normal. Calcific aortic stenosis^{34,35} and mitral stenosis of rheumatic origin³⁶ have been reported in elderly patients who reached advanced ages without suffering any ill effects from their previously acquired valvular disease.

Microscopic changes with age. The microscopic changes of involution have been well summarized by Warthin³⁷: there is a loss of power of cell division with fewer mitoses, a quantitative atrophy with fewer and smaller cells, condensation of the chromatin of the nucleus, nuclear pyknosis, vacuolation and karyolysis, and lipoid deposition in the cytoplasm may be observed. It should be stressed, however, that such changes are usually most marked where the blood supply is insufficient.³⁸ The striations tend to disappear about the nuclei, and an increased amount of pigment may be observed at the poles of the muscle cells. The conducting system is unaffected by the general atrophy. Hyaline fibrosis, with a loss of water, is said to occur, but Hastings et al.,³⁹ studying the water content of the left ventricular muscle in puppies and adult dogs, found no differences. Miller and Perkins⁴⁰ showed an increase in thickness of the left atrial endocardium and a striking increase in elastic tissue fibers, mainly in the auricles but also in the ventricles. Finally, vascular changes such as atherosclerosis, loss of elastic tissue and muscle cells, and calcium deposition are frequent.

Coronary arteries. Whether arteriosclerosis is to be regarded as a senescent change or due to some disease of unknown origin is unsettled. Hirsch and Weinhouse⁴¹ point out that even when only the media of the aorta are taken (avoiding adventitia and the variation with disease in the intima), there is an increased percentage of lipids, particularly cholesterol esters, with age. In a study of routine blood cholesterol and cholesterol esters in 150 persons with a mean age of seventy-seven, 60 per cent had levels higher than 200 mg. (40 per cent free).⁴² The lipid deposits in atherosclerosis seemingly result from nonselective deposition of plasma lipids. It is, however, peculiar that cholesterolemia such as is seen in diabetes mellitus or totally thyroidectomized individuals may be associated with normal coronary arteries. The absence of arteriosclerosis in the Chinese, who not only eat a low cholesterol diet but, as Snapper⁴³ points out, have low blood cholesterol values, may be explained in part by the age of the patients studied.

Whether or not coronary arteriosclerosis is a disease, it is a striking fact that occlusions are found in 40 per cent of males over fifty-five years of age. Thus, as age is prolonged, there is a tendency for completely healthy coronary arteries to become

fewer and for progressively severer changes to appear.⁴⁴ In Akerson's⁴⁵ series the peak of frequency of disease was found in the ninth decade in men and in the eighth in women. On the other hand, healthy coronary arteries are not unusual in old persons.⁴⁶ The development of anastomoses does not occur with progressive age, and this may explain in part the increased mortality in initial attacks of myocardial infarction in old persons. It is of some interest that no correlation between changes in the radial artery and coronary-artery disease exists⁴⁷; in marked cases of the latter the radial arteries may present a minimal degree of arteriosclerosis, both anatomically and clinically.

PHYSIOLOGIC CHANGES

Pulse rate. The pulse rate is said to increase slightly in persons above the age of sixty-five.⁴⁸ Humphry⁴⁹ noted an average pulse rate in women over eighty of 78 to 79, while in men it was 73. In 52 centenarians the average pulse rate was 74 to 75.

Carotid sinus. The carotid-sinus reflex becomes more sensitive with age.⁵⁰ Sigler⁵¹ has attempted to use the degree of sensitivity as a test for the presence of coronary-artery disease and angina pectoris. Although it is true that many patients with angina pectoris have a sensitive carotid sinus, approximately a third do not.⁵²

Cardiac output. Lewis⁵³ found no change in cardiac output in 100 men aged forty to eighty-nine. Thus the mean cardiac index, the cardiac output (in liters) divided by the surface area (in square meters), was 2.3 in the eighth and 2.2 in the ninth decade respectively. Two persons aged ninety-one and one aged one hundred and one had indices between 2.0 and 2.3. The small decline is due to a drop in oxygen consumption in the aged. Previous observers had noted in older persons a lessened oxygen consumption.^{54,55} The normality of the cardiac output at rest is, however, no index of the heart's ability to act under stress.

Vital capacity. Several studies on the effect of aging on the vital capacity show that this measurement is only slightly decreased from forty to fifty years, with a rapid and progressive decline in the older age group.⁵⁶⁻⁵⁸ Thus the vital capacity of otherwise healthy men in the ninth decade of life is found to be about half the accepted standards.^{56,57} A similar decrease in older men occurs in total lung volume, with a concomitant increase in residual air and mid-capacity (functional residual air).⁵⁹ The alterations in respiratory dynamics are a reflection of other changes in structure and function that occur with aging, namely, degenerative changes in the thorax and spine, with limitation of respiratory excursion, obesity and elevation of the diaphragm and loss of elasticity of the lung parenchyma and bronchial tree. If these anatomic changes are accepted as part of the process of normal aging,

in the changes in respiratory measurements that they produce must be interpreted as normal, and standards must accordingly be corrected for age. This is essential for the clinical interpretation of these measurements, since the changes of aging of cardiorespiratory disease are in the same direction.

Acid-base balance. There are no significant changes in acid-base balance. Thus 33 of 50 persons aged seventy or over studied by Dogliotti and Pitts⁵³ had a normal blood pH. The remainder showed changes in pH to the side of either uncompensated acidosis or alkalosis. With exercise old persons, however, there may be an abnormal accumulation of lactic acid and a decrease in alkaline reserve,⁵⁴ indicative of an inadequate increase in cardiac output during exercises, that is, diminished cardiac reserve.

Venous pressure and circulation time. The venous pressure is normal in the aged.^{60, 61} The circulation times, as measured with the fluorescein⁶² and indigo⁶¹ methods, show a definite trend toward lower rates with increasing age, but they remain within the normal upper limit of 20 seconds. On the other hand, the velocity of blood flow through the lungs shows no constant relation to the age of the patient.⁶³

Velocity of pulse wave. Studies of the pulse wave velocity of the radial artery and the aorta showed an increase with age.⁶⁴⁻⁶⁶ This is associated with an increase in elasticity, which may be halved at the age of sixty.

CLINICAL EXAMINATION

False diagnosis of heart disease. A diagnosis of congestive heart failure in the aged based on dyspnea, slight cyanosis, basal rales and a palpable third edge is too frequently made. Pulmonary diseases such as emphysema, pulmonary fibrosis, and chronic bronchitis and atelectasis are, on the contrary, much oftener responsible for these symptoms and physical findings. Peripheral edema, particularly that occurring as an isolated finding, is more usually due to nutritional deficiencies, varicose veins, intra-abdominal tumors and obesity than to congestive heart failure. Chest pain, consequent to cervical or thoracic osteoarthritis, hiatus hernia or gall-bladder disease, is too frequently labeled angina pectoris. A careful history usually all that is needed to differentiate these conditions.

Heart size. A normal-sized heart, although it does not exclude the presence of coronary-artery disease and angina pectoris, does rule out most other forms of cardiac disease. In the aged it is difficult, however, to be sure of the heart size by percussion and palpation. Emphysema probably poses the greatest difficulty in this regard. A markedly hypertrophied heart, as evidenced by an impulse beyond the midclavicular line or a

corresponding left-border dullness, is not normal. Dullness to the right of the sternum may be evidence of enlargement or dilatation of the right side of the heart. An abnormal band of dullness at the base (over 6.0 cm.) is evidence of ectasia of the aorta.

Heart tones. The heart tones are decreased in loudness in the aged.⁶⁷ Emphysema probably plays a role in this phenomenon, although Garguilo and Allende⁶⁸ say that there is a physiologic decrease in the intensity of the heart sounds in old age. Changes in the tones, such as accentuation and disappearance of the second aortic tone, have the same significance in the aged as in younger persons. Accentuation of the second pulmonic sound is indicative of pulmonary hypertension.

Heart murmurs. It is apparent from a consideration of the anatomic data previously cited that soft systolic murmurs at the mitral or aortic area might be expected to be heard in many older people. A loud mitral systolic murmur, however, must be interpreted as due to dilatation of the mitral ring, secondary either to ventricular dilatation or to changes in the mitral valve; an apical diastolic murmur is, as in younger persons, diagnostic of mitral stenosis. Aortic stenosis, a frequent lesion in the elderly, may be diagnosed when two of the following three signs are present: a systolic aortic murmur over the aortic area transmitted to the neck or precordial area, or both (calcium deposits are said to produce a rasping or musical quality to the murmur); a systolic thrill in the aortic area that may be brought out by bending the patient forward; and an absent or diminished second aortic tone. Willius⁶⁴ has divided calcareous aortic stenosis into four grades anatomically and clinically. A division into only two groups is probably more useful. The severe grades of calcareous aortic stenosis showed marked cardiac hypertrophy: a loud, rasping systolic murmur heard over the entire thorax and loudly transmitted to the carotid arteries, a coarse systolic thrill anteriorly in the second and third right interspaces, an absent second aortic tone, an aortic diastolic murmur in a third of the cases and, if aortic insufficiency and hypertension are absent, a small peripheral pulse and low pulse pressure. The milder grades of calcareous aortic stenosis presented a rough and fairly loud murmur heard best in the aortic region and transmitted usually into the carotid arteries. There was usually no accompanying systolic thrill or change in the aortic second tone, and cardiac hypertrophy was slight or absent. It should be stressed, however, that these findings were based on hearts showing definite calcareous aortic stenosis and were not compared to the findings in patients presenting only atheromatous changes in the aorta and aortic valve or annulus fibrosis. A systolic-diastolic murmur and thrill may occur in arteriosclerotic aneurysms and senile ectasia of the thoracic aorta.⁶⁹

but may be differentiated by the presence of a good aortic second tone and by x-ray visualization.

Rhythm. The heart rhythm in the aged is normal. Although extrasystoles do occur, there is no clear evidence that they occur more frequently in the aged than in the young. Paroxysmal arrhythmias, such as fibrillation and flutter, are seen more frequently in the aged, particularly in patients suffering from pneumonia and thyrotoxicosis.⁷⁰ When the rate is over 150, the presence of anginal pain with the arrhythmia is highly suggestive of the presence of coronary-artery disease.⁷¹ Persistent auricular fibrillation should arouse the suspicion of thyrotoxicosis. It is significant, however, that cases of persistent auricular fibrillation lasting as long as twenty-five years have been reported.⁷²

Blood pressure. Reported studies of the blood pressure present conflicting results. Some investigators found no change in average or modal blood pressure with increasing age.^{73, 74} Robinson and Brucer⁷⁴ excluded, however, all pressures of 140 systolic, 90 diastolic, and above. On the other hand, Master et al.,⁷⁵ in a series of nearly 15,000 men and women, found two thirds (males) to three fourths (females) of persons seventy years old and over to have blood pressures over 150 systolic, 90 diastolic. Other reports of smaller groups likewise contain a large percentage of persons in the older age group with systolic hypertension.^{76, 77} The systolic hypertension is probably compensatory for the loss of elasticity in the aging blood vessel walls. It is of some interest that the life expectancy of persons with systolic hypertension was of the same order as for those with normal blood pressure.⁷⁶ Thus it is probable that the presently accepted standards of normal blood pressure in the aged are too low. In nonhypertensive individuals, the diastolic blood pressure shows a tendency to fall with age,⁷⁶ with a resultant marked increase in pulse pressure. This is probably due to the rapid fall of pressure within the arteries during diastole,⁷⁸ for which compensation does not occur because of the diminished elasticity of the blood vessels.

Corrected erythrocytic sedimentation rate. The sedimentation rate is widely used in the diagnosis of myocardial infarction. It must be remembered, however, that there is a definite rise in the corrected erythrocytic sedimentation rate with age alone.⁷⁹ Values up to 0.7 mm. per minute by the Rourke-Ernstene method are apparently normal above the age of fifty, whereas in younger individuals the normal is 0.08 to 0.35 mm. per minute.

Electrocardiogram. The paucity of knowledge of the electrocardiographic changes consequent to age alone is reflected in the fact that most of the standard texts of electrocardiography have no listings for subjects as "aging," "aged" or "old age." Certain changes are known to occur, however, with sufficient frequency in the aged in the absence of other manifestations of cardiac disease to be

regarded as normal. Many of these same changes, nevertheless, are considered to be definite, although minor, abnormalities when they are found in younger subjects.

The most frequent of these changes in the electrocardiogram of the aged is a shift in the electrical axis of the heart to the left (or counterclockwise); this has been observed in well over 50 per cent of older patients.⁸⁰⁻⁸⁵ An associated but less frequent finding with the same significance is a prominent QS wave in Lead 3, and an inverted T₁. These changes probably derive from a more transverse position of the heart secondary to flattening of the diaphragm and perhaps also in part from a relative hypertrophy of the left ventricular mass with age in relation to the right ventricle. Thus, in a group of patients with marked left-axis deviation, Faulkner and Duncan⁸⁶ found normal-sized hearts by x-ray study in more than a third, whereas almost another third showed hearts that were anatomically normal.

Extrasystoles occur in about a third of elderly patients,⁸⁷ and as in younger groups, they constitute the usual electrocardiographic arrhythmia. Those of ventricular origin are about twice as common in occurrence as those of auricular origin. They assume pathological significance when frequent or when they show coupling or other rhythmic occurrence or multiple foci of origin.

With aging there is a slight increase in transmission time through the entire conduction system of the heart, reflected in a PR interval that frequently exceeds 0.20 second and an intraventricular interval that is often greater than 0.10 second.^{88, 89} Tendency to low voltage is found in all the component waves of the electrocardiogram.⁸⁵

There is less agreement concerning the frequency or significance of other isolated electrocardiographic findings in the aged; these include low or inverted T waves in leads other than Lead 3, deviation of ST segments, the duration of the QRS complex beyond 0.11 second, the presence of prominent Q waves in leads other than Lead 3, right-axis deviation, auricular fibrillation and marked bradycardia. Indeed, there is little agreement as to their significance in healthy young persons.⁸⁸

It is apparent from the above that there is no agreement among observers about the definition of the normal electrocardiogram for healthy old persons and about the frequency of occurrence of normal tracings in various age groups. Thus the incidence of abnormal electrocardiograms in groups of aged persons is cited by various authors as 0 per cent,⁸⁷ 26 per cent,⁸⁰ 41 per cent,⁸⁹ 67 per cent,⁸⁵ 85 per cent⁸² and 97 per cent.⁹⁰ Much of this discrepancy is accounted for by the inclusion in some series of old persons with definite clinical evidence of serious heart disease, such as cardiac enlargement, congestive failure or myocardial infarction,^{81, 91} and by great variability in the criteria of electro-

radiographic normality. The crux of the situation is that standards have not yet been established for older age groups. It appears, however, that over one-fourth of aged persons with no evidence of heart disease by careful history and physical examination show abnormalities in the electrocardiogram.^{50, 52, 53}

There are nowhere in the literature any reports of clinical, electrocardiographic and detailed pathological correlations in aged hearts, and it is therefore of some interest to cite certain preliminary observations in this regard.⁵¹ A survey was made of the records of hearts from 100 consecutive patients aged sixty-five and over studied at the Beth Israel Hospital by the injection-dissection technic of Schlesinger.⁵² In 29 cases the hearts showed coronary arteries essentially free of disease, and in 17 of these the heart could be regarded as clinically and pathologically normal. Ten of this group of patients with "normal" hearts were studied electrocardiographically. These patients did not differ in age or sex distribution from the entire group of 100. Five of these had entirely normal electrocardiograms, 2 had low T waves in Lead I, 2 had inverted T waves in Lead 4, and 1 showed the pattern of left-bundle-branch block. The last was the only patient in this group showing any increase in conduction time over the accepted standards for all ages; this is in contrast to the findings cited above. Left-axis deviation was present in 3 patients, right-axis deviation in 1, and in the remaining 6 the axis was normal. Three patients showed low voltage, and 2, ventricular premature beats. These observations, because of the small group involved, have no statistical significance. They illustrate, however, the type of study that will be necessary for the establishment in geriatric electrocardiography of standards that will separate disease and changed function due to normal aging.

To summarize, the following generalizations are thought to be of more significance than the few non-specific changes that may be found in the electrocardiograms of aging hearts. First, there is no electrocardiographic pattern of the senile or aging heart.⁵⁴ Second, the electrocardiogram even in the very aged may be identical in all respects with that of youth.⁵⁵ As in any age group, serious and far-advanced heart disease may exist without any reflection of its magnitude or even its presence in the electrocardiogram; this is especially true of coronary-artery disease.⁵⁴ Third, adequate clinicopathological and electrocardiographic correlations are needed in the aged as a basis for diagnostic and prognostic conclusions. Such studies might well be aided by a widespread use of electrocardiograms in the routine clinical examination of patients of middle age and beyond. Finally, it is evident from the foregoing that, even more in the aged than in young patients, the electrocardiogram must be viewed as a part of the total evaluation of the pa-

tient, which should include careful history-taking and physical examination and correlated laboratory studies. Nevertheless, the diagnosis of coronary sclerosis will be missed in a fair number of apparently healthy elderly persons.

X-ray studies. Certain minor changes have been described in the x-ray appearance of the heart and great vessels in the aged.⁵⁵ As the diaphragm becomes higher, the heart assumes a more horizontal position and the contour of the left ventricle becomes slightly more prominent. The aorta in its ascending portion increases in length and circumference and may show tortuosity. Dilatation may become so marked that the diagnosis of arteriosclerotic aneurysm must be made.⁷⁰ Cardiac pulsations do not have the vigor characteristic of earlier years. Calcification may be seen in the aorta and aortic knob, in the heart valves or valve rings or even in the coronary arteries; when present in the valve leaflets, it assumes clinical significance.

There is no agreement concerning the heart size and the changes that occur with aging, even with respect to pathological data, as the discussion above indicates. If such changes do occur constantly, it remains to be seen if they are of such magnitude as to be detectable by x-ray technics and standards for determining heart size. The more reliable of these standards are now based only on height and body weight.⁵⁶ For the present, therefore, significant or progressive increase in heart size by x-ray studies, even in the aged, should be interpreted as being generally indicative of heart disease.

TREATMENT

General considerations. As we have noted above, although there has been a large increase in the number of people living to the age of sixty-five or over, no increase in life expectancy for this group has been observed.

It should be stressed that the majority of persons in this age group have coronary-artery disease. Thus in the 100 cases that we studied,⁵¹ 63 patients had significant coronary-artery disease and the cause of death was cardiac in the majority. It is more striking that no clinical diagnosis of heart disease was made in 37 cases. In 15 of the latter cases the hearts showed extensive coronary-artery narrowing or occlusion, or both; in 1 case, that of a patient with lymphatic leukemia, a recently healed apical infarct was found. It is thus clear that although no clinical evidence of coronary-artery sclerosis may be present in a given patient, all elderly persons should be handled as if they had some degree of that disease. Progress would involve, therefore, among other things, preventive measures designed to prevent disturbances of function, congestive heart failure and acute cardiac accidents.

Surgery. The management of cardiac patients who require major surgery has been reviewed by

Blumgart.⁹⁷ Much of the discussion is pertinent to the older patient with no functional cardiac disturbance but with the statistical possibility of coronary-artery disease. The prevention of postoperative acute myocardial infarction depends on the avoidance of shock, which may follow hemorrhage, and severe infection. Hypoglycemia is of serious import in this regard in diabetic patients submitted to surgery. Hypotension associated with spinal anesthesia should be prevented by adequate use of sympathomimetic drugs having little effect on cardiac work, such as Paredrine or Neo-Synephrine. It should be stressed that rarely does an aged surgical patient die a primary cardiac death. Thus, Wilcox and Clagett⁹⁸ list 1204 patients over sixty-five years of age who underwent operations with a mortality of only 8 per cent for benign conditions and operable carcinoma. It was striking that only 20 per cent, however, failed to have a significant postoperative complication, such as thrombophlebitis, pneumonia, embolism, atelectasis or a cerebral or renal complication. Brooks,⁹⁹ however, points out that a third of a group of patients over seventy requiring abdominal section died in the hospital. Moreover, the survivors realized only a small fraction of their life expectancy. Wangenstein¹⁰⁰ stressed, on the other hand, the safety of multiple operations in patients adequately prepared with a preoperative period of high-protein, high-carbohydrate and low-fat feedings, adequate hydration and satisfactory electrolyte balance. It should be borne in mind, however, that edema may accumulate in a patient with poor cardiac reserve who is given a large amount of salt preoperatively or postoperatively, since approximately 1.0 gm. of salt retains 100 cc. of water.

Prevention of congestive failure. In last year's review¹⁰¹ certain forms of curable heart disease were discussed. It should be stressed that anemia and nutritional deficiency may have a deleterious effect on the normal heart, particularly in the aged. Dietary restriction is frequent in the aged because of the lowered metabolic requirements, changes in gastrointestinal function, depressed appetite, loss of teeth, lack of exercise and so forth. The recognition and adequate therapy of anemia and nutritional deficiency before cardiac complications such as angina pectoris and congestive heart failure have occurred are important. Tuohy¹⁰² has stated that the competence of healthy old people is largely a matter of nutrition. He emphasized the error in the idea that the elderly should be abstemious, while advocating a restriction of fat content in the diet of an inactive patient to 10 per cent of the necessary calories.

Burwell¹⁰³ summarized some of the factors tending to precipitate heart failure in patients with asymptomatic heart disease. The most important of these are infections, particularly respiratory infections, associated with fever, tachycardia and

cough, since they cause increased cardiac work and possibly a depression in cardiac efficiency. Bed rest, adequate chemotherapy and maintenance of oxygenation should minimize the injury to the heart.

Bed rest. Much has recently been written concerning the abuse of bed rest in elderly patients.¹⁰⁴⁻¹⁰⁷ It has been stated by Dock¹⁰⁴ that bed rest claims more lives than all other therapeutic agents added together. The evidence is, however, not conclusive, for many patients do poorly in the hospital because they are worn out by overvigorous investigation and overfrequent examination. The energy expended by a patient in a complete gastrointestinal roentgenologic study, for instance, is exhausting, particularly to an old person. Drastic changes in eating habits and in hours of sleep made necessary by hospital routine, together with the too frequent use of sedatives, may also act deleteriously in the aged. Particular emphasis has been placed on bed rest as a cause of occurrence of peripheral and pulmonary emboli.¹⁰⁴ Actually, however, the cause of thrombophlebitis is unknown, and it is perhaps as unscientific to ascribe the cause to bed rest as it is to say that bed rest has nothing whatever to do with its occurrence.

It is clear, nevertheless, that prolonged and absolute bed rest leads to muscular, possibly including cardiac, weakness and atrophy, in addition to pulmonary and other complications. The period of convalescence may therefore be unnecessarily prolonged. Good clinical judgment is thus of paramount importance in this matter.

Physical exertion. One has only to look at the obituary notices in newspapers to be impressed by the effect of severe physical exertion in elderly people. Boas¹⁰⁸ in particular has stressed the occurrence of acute myocardial infarction after severe physical or emotional stress. Aged patients should be warned to avoid such strain, particularly in the winter and also when they are fatigued.

On the other hand, an important and often neglected aspect of prolonging the useful lives of the aged is making living worth while for them. Too often they live in an insulated atmosphere that promotes physical and mental atrophy because of an imposed isolation. Psychometric studies actually demonstrate a wide range of individual variations in the aged in intellectual ability, physical skill and interests.¹⁰⁹ The family physician can play an important role in helping to devise a program of activities for his elderly patients that is adapted to these individual variations in mental and physical capacities.

EDITH E. PARRIS, *Assistant Editor*

CASE 30481

PRESENTATION OF CASE

A fifty-seven-year-old housewife entered the hospital because of intermittent sharp pain in the lower abdomen.

The patient was perfectly well until one month before entry, when she was troubled by mild lower abdominal "cramps" of several days' duration. Her bowels remained regular, however, with at least one bowel movement a day. She noted that there was a fair amount of mucus passed with the stools. Two weeks before entry she began to have sharp colicky pains, which started in the right lower quadrant and passed across to the left lower quadrant. These caused her to double up in agony, but no nausea or vomiting was present. The pains lasted throughout the day, and with each attack she had the urge to move her bowels, though nothing was passed by rectum. Her doctor made a diagnosis of "abdominal stasis" and gave her a cathartic. This resulted in a copious bowel movement and complete relief. She continued to eat heartily and to have a daily bowel movement until one week before entry, when her bowels did not move for a day and she took a cathartic. The next day she again had an attack of lower abdominal pain similar to that of the first attack. She took several doses of milk of magnesia, which made the pain worse. Nausea and vomiting set in, and she vomited green-colored mucus. Five days before entry she had a normal bowel movement, with relief from pain. She still felt poorly, however, and had lost her appetite. Several enemas were poorly retained and brought little return. Four days before entry her doctor felt a tender "bunch" in the left lower quadrant and advocated hospitalization. She had

had no further recurrences of pain and had had daily bowel movement. No blood had been noted in the stools. She had lost an estimated 20 pounds in weight in the month before entry.

She had had a right oöphorectomy and salpingectomy for "cyst" many years before admission followed by removal of the other internal organs some years later.

Physical examination showed a well-developed, rather obese woman in no apparent distress. The heart and lungs were normal. The abdomen was negative. Peristalsis was normal. There was slight tenderness in the left lower quadrant to deep palpation during pelvic examination. A firm, reddish, pedunculated mass, the size of a small pea, protruded from the depression in the apex of the vagina. Rectal examination revealed a walnut-sized, irregular, smooth, hard, painless mass on the anterior rectal wall about 10 cm. above the sphincter.

The blood pressure was 140 systolic, 80 diastolic. The temperature was 100°F., the pulse 84, and the respirations 28.

Examination of the blood showed a white-cell count of 10,000, with 90 per cent hemoglobin. The urine was acid, with a specific gravity of 1.024; it gave a + test for albumin and there were 8 red cells per high-power field in the sediment. A Hinton test was negative. The blood chemical findings were normal. X-ray films of the chest and intravenous pyelograms were negative. A barium enema showed passage of the barium through the rectosigmoid junction to the lower sigmoid, at which point there was a narrowed portion of intestine through which a thin stream of barium passed. There was a suggestion of a shelf deformity, but no evidence of ulceration (Fig. 1). Proctoscopic examination revealed normal rectal mucosa up to 13 cm., where an extraluminal obstruction was found encroaching anteriorly. The proctoscope could not be passed beyond this lesion. The mucosa immediately beneath was granular and hyperemic but intact.

On the fifth hospital day the patient developed diarrhea and a fever of 101°F. Examination at that time was essentially as before. She was given 5 gm. of sulfasuccidine three times daily, and on the tenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. OLIVER COPE: This patient had intestinal obstruction of one month's duration. The point of

*On leave of absence.

struction was the pelvic portion of the large rel.

We are given no detailed information regarding previous pelvic operations. I take it that these operations were not performed in this hospital and it we have neither a surgical nor a pathological report. Knowledge of the previous pelvic disease might make a difference. It might be related to the anatomic abnormality reported in the vaginal examination, or the latter may be a red herring thrown across our path, it and the previous pelvic disease having nothing to do with the present complaint. In the physical examination, the uterine cervix is not mentioned. One must therefore assume that the

effort to reduce the growth of organisms and, therefore, the volume of feces in the colon. Presumably the operation was for relief of the obstruction.

In order to arrive at a diagnosis it is necessary to consider all those lesions that can produce obstruction in the sigmoid. The x-ray studies as reported tend to exclude primary carcinoma of the sigmoid. Since the x-ray examination is extremely important, I shall ask Dr. Schulz if he has anything to add to the report. I trust that he will comment on the absence of ulceration and on the nature of the constriction.

DR. MILFORD SCHULZ: There is an area of narrowing in the sigmoid. I do not see the shelf that was

FIGURE 1 Roentgenogram Following Barium Enema
Arrows indicate area of narrowing in sigmoid.

hysterectomy had been a total one. If this is true, the mass palpated on the anterior rectal wall did not represent the cervix but an abnormal mass.

The negative intravenous pyelogram is important. We may assume in the first place that the disease is not primary in the urinary tract and, secondly, that the lesion in the pelvis did not affect either the ureter or the bladder. Had the hysterectomy been one for carcinoma of the cervix and had the mass been a recurrence of the carcinoma in the pelvis, one might well have expected the mass to have been more to one side or the other and to have produced obstruction of one of the ureters, with hydronephrosis.

It is obvious that the physician in charge made a diagnosis of incomplete obstruction. The patient was carried for ten days on sulfasuccidine in an

effort to reduce the growth of organisms and, therefore, the volume of feces in the colon. Presumably the operation was for relief of the obstruction.

DR. COPE: Enough barium got by the loop for a satisfactory examination?

DR. SCHULZ: Yes; the bowel proximal to the narrowing is not widely dilated, and the obstruction is not complete. No diverticulums are evident.

DR. COPE: The fact that no diverticulums were visualized does not in itself exclude diverticulitis, but if the obstruction in this patient was due to diverticulitis, I should have expected a more extensive involvement of the bowel than what is present. The involved area is limited, the upper sigmoid not being involved.

DR. SCHULZ: The proctoscopic examination describes the lesion in the rectosigmoid. The lesion demonstrated here is higher up.

DR. COPE: Is there any evidence by x-ray of an extrinsic mass? I do not want to pin you down too far. Do I understand that you would not ascribe the lesion to carcinoma because of the absence of ulceration, or to diverticulitis because of the lack of involvement of the other part of the bowel?

DR. SCHULZ: I do not believe that one can rule out carcinoma, especially in view of the questionable shelf that was described. Certainly its appearance is not characteristic.

DR. COPE: From both the physical and x-ray examinations the abnormal mass was small and the area of the bowel involved was short. A malignant lesion is a better explanation than an abscess. I am not sure, however, whether the mass was intrinsic or extrinsic in relation to the sigmoid. Thus far I favor a diagnosis of primary cancer of the sigmoid, but I cannot exclude either diverticulitis of the sigmoid or an extrinsic lesion causing obstruction of the sigmoid.

In the latter category three conditions should be discussed. In the first place, endometriosis of the pelvic peritoneum can involve the sigmoid in such a way as to cause obstruction. This would be unusual in a woman past the menopause, for in the absence of continued ovarian activity the endometrial-like tissue should undergo atrophy. There are, however, endocrine sources other than the ovary for estrin-like hormones, such as the adrenal cortex. In the second place, one should consider gravitational metastases with involvement of the sigmoid. The primary lesion for such a carcinoma might be the stomach or some other organ in the upper abdomen. And, third, I should like to mention, for I have seen it once, adenoacanthoma arising in the cervix and later involving the large bowel. In 1931, I operated on a woman for what appeared to be a primary malignant tumor of the large intestine producing obstruction. Two years previously she had had an adenoacanthoma of the cervix excised surgically. At my operation an adenoacanthoma of the large bowel, presumably a metastasis from the primary lesion, was disclosed. In the absence of knowledge regarding the previous pelvic lesion, one cannot afford to make such a diagnosis. I am left with the only tenable diagnosis, that of a primary malignant tumor of the lower sigmoid.

DR. LELAND S. McKITTRICK: Some years ago I resected a sigmoid for a woman in her early sixties; the lesion, which we had interpreted as a carcinoma, proved to be an endometriosis. There was no other evidence of ovarian activity. She had the menopause in the usual way — over a long period of years. Is there any less likelihood of endometriosis in a person with a surgical menopause than in one who has had a normal one?

DR. COPE: I should think that there was. In producing the surgical menopause, the operator would presumably have removed in his operation the majority of endometrial implants. Less tissue would have remained to contract and to produce bowel obstruction.

Was there active tumor proliferation or only scarring in your case?

DR. McKITTRICK: There was real tumor formation. I cannot give the details of the microscopical findings, but it was more than just scarring.

DR. COPE: As I have said, there are the other endocrine sources for continued mild stimulation of the endometrium, such as the adrenal cortex.

DR. ANNE FORBES: Are you sure that no one gave this patient estrin?

DR. COPE: That is a good point. Estrin therapy after the menopause would have reactivated endometrial tissue. If this patient had received estrin in large doses, she might have developed a pelvic endometrial tumor.

DR. FRANCIS D. MOORE: So far as we know the patient had not received estrin therapy. The pelvic operation was done many years before entry. The mass in the apex of the vagina was just a mucosal tab.

DR. COPE: The tab was a red herring.

DR. MOORE: Our line of reasoning was similar to that of Dr. Cope. The mass felt by rectum and seen by proctoscopy was caused by extrinsic pressure of a neighboring loop. We thought preoperatively that it was in all likelihood a carcinoma of the sigmoid. At operation we did not find anything to change our opinion. The pelvis was surprisingly free — no mass and no extensive inflammatory or neoplastic disease. There was a small sclerosing lesion that had every appearance of an annular carcinoma of the sigmoid. A combined abdominoperineal resection was done after freeing it. After removal, the bowel was opened, and looking at it grossly, we still thought that we were dealing with a carcinoma of the sigmoid.

CLINICAL DIAGNOSIS

Carcinoma of sigmoid.

DR. COPE'S DIAGNOSIS

Carcinoma of sigmoid.

ANATOMICAL DIAGNOSIS

Diverticulitis of sigmoid.

PATHOLOGICAL DISCUSSION

DR. RONALD C. SNIFFEN: Dr. Moore removed about 48 cm. of rectum and sigmoid. The rectum was normal. Above the peritoneal reflection there was an 18-cm. segment of sigmoid, which looped down anteriorly to fix itself against the anterior portion of the sigmoid near the point of the peri-

fecal reflection. Here, there was a mass of adhesions, which apparently formed the tumor that was seen. Throughout the sigmoid there were many diverticula, and we found that sinus tracts ran to the mass from both the distal and proximal portions of the sigmoid loops. The mass consisted of chronic inflammatory tissue and was undoubtedly due to diverticulitis. At the point where the proximal portion of the sigmoid was fixed to the inflammatory mass there was an appreciable narrowing of the lumen.

DR. COPE: Dr. McKittrick, how often do you see sharply localized diverticulitis that is difficult to distinguish from carcinoma at operation?

DR. MCKITTRICK: I do not know, but I can tell you that I have just sent a patient home for whom at the end of operation I gave the family a poor prognosis because I thought that he had incurable carcinoma. I did not open the specimen and was overwhelmed when the report was diverticulitis. I see it infrequently enough so that I was badly misled, but frequently enough so that it is not a rarity.

DR. COPE: The X-ray Department does better than we do. Dr. Schulz, if I am correct, was against cancer because of the appearance of the mucosa.

DR. MCKITTRICK: On the other side of the ledger is the fact that we not infrequently discover an abscess from a diverticulitis when the radiologist has found nothing.

DR. SCHULZ: We do not see a diverticulum unless it is filled with barium. In this case, the diverticula did not fill. An intact mucosa is helpful, if you can be sure of it, and likewise, a good shelf.

CASE 30482

PRESENTATION OF CASE

A fifty-eight-year-old single nurse entered the hospital for study.

For fifteen years the patient had had intermittent sensations of fullness in the right upper quadrant of the abdomen and vague distress after meals. Nine years before admission a gastrointestinal series was negative. One year later she started to have intermittent gross melena attributed to hemorrhoids. This condition persisted. About one year before entry the distress in the right upper quadrant became severer. There were definite jaundice, light-colored stools and dark urine for one week, at the end of which time a cholecystectomy and cholecystostomy were performed at a hospital in another city. Postoperatively she had a stormy course, with increasing jaundice and clay-colored stools, which eventually, however, cleared up. She apparently remained well, except for occasional bouts of epistemic distress, until ten weeks before entry when she developed pruritus, followed four weeks later by frank jaundice, increasing light-colored stools

and dark-colored urine. One week before entry she was admitted to a community hospital where she was treated medically, with amelioration of the symptoms. Since the jaundice persisted, she was transferred to this hospital. She had lost 30 pounds in weight in eleven months. The only vomiting she had had was induced, and she thought that it relieved the distress in the right upper quadrant. She had had no chills or fever.

Physical examination showed a thin, deeply jaundiced woman. The lungs were clear. The heart was normal in size. The liver edge was palpable three fingerbreadths below the costal margin. Slight tenderness was elicited in the right upper quadrant, but no masses were palpable.

The blood pressure was 144 systolic, 82 diastolic. The temperature was 99°F., the pulse 76, and the respirations 20.

Examination of the blood showed a white-cell count of 5700, with 71 per cent neutrophils and 18 per cent lymphocytes; the hemoglobin was 8.5 gm. per 100 cc. The urine was normal. A blood Hinton test was negative. The stools were reddish-brown and gave a ++++ guaiac test. The serum protein was 6.2 gm. per 100 cc. The serum bilirubin was 6.65 mg. per 100 cc. direct, and 8.8 mg. indirect.

Plain films of the abdomen and chest were negative. A barium enema showed normal filling of the rectum and rectosigmoid. Just beyond the rectosigmoid junction there was a constant area of narrowing that appeared to be due to a filling defect on the superior wall of the sigmoid measuring about 4 cm. in length. On one film a shelf could be seen at the distal end of this defect. The remainder of the colon showed no abnormality. The transverse colon dipped down into the pelvis to overlay the abnormal area, which was therefore not visible in the subsequent films. Post-evacuation films showed only moderate contraction of the colon and a large amount of fecal material was still visible in it; the sigmoid was obscured by the transverse colon. In all the films the upper abdomen was unusually dense, but no soft-tissue outline was demonstrable. Re-examination of the colon after the introduction of air showed numerous small rounded areas of diminished density that may have been due to fecal material intermingled with the barium.

The patient was given several transfusions, and on the fifteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. ROBERT R. LINTON: We have a patient fifty-eight years of age whose symptoms began fifteen years before entry, with fullness and distress in the right upper quadrant after meals. Nine years before entry a gastrointestinal series was done, and I presume that it was negative. The examination was probably limited to the stomach and small bowel since nothing is said about the colon. It would

be interesting to know whether she had had a barium enema at that time. The statement "One year later she started to have intermittent gross melena attributed to hemorrhoids" needs a little comment. I do not believe that one ever ought to attribute bleeding from the rectum to hemorrhoids until all other possibilities have been ruled out. It is extremely dangerous in a patient with hemorrhoids to say that the bleeding is coming only from hemorrhoids without a complete rectal and sigmoidoscopic examination, since it may be coming from a lesion higher up in the colon that is often overlooked until it becomes inoperable. One year before admission the distress in the right upper quadrant became severer and associated with it were jaundice, clay-colored stools and dark urine. At that time a cholecystectomy and choledochostomy were done at an outside hospital. The postoperative course following these operations does not seem just right for cholecystitis and cholelithiasis, in that it states that she had a stormy convalescence with increasing jaundice and with clay-colored stools, which eventually cleared up. Ordinarily when one operates on the gall bladder and drains the common duct, as I presume was done in this case, a tube is sutured into the common duct so that the patient's bile can drain externally rather than into the duodenum. If the patient were treated in this manner and if the jaundice was purely obstructive, it is surprising that she developed increasing jaundice. It is possible, of course, if the jaundice was due to intrahepatic disease, that the operation produced additional liver injury, thus causing the jaundice to become more pronounced.

DR. FRANCIS D. MOORE: I can clear up that point. She did have a tube put in, and it was after it was taken out that the jaundice appeared.

DR. LINTON: That is an important fact to know, because it probably means there was some obstruction in the distal part of the common duct, either postoperative stricture, inflammation, stone or malignant growth, that was temporarily occluding the outlet of the common duct.

The patient was apparently well for most of the following year. Ten weeks before entry to this hospital, however, she developed pruritus, and six weeks before admission, she again had jaundice, with light-colored stools and dark urine. It is interesting to note that in the previous year she had lost 30 pounds and that she had had no chills or fever. If she had had a common-duct stone I think that she probably would have had an associated cholangitis, with chills and fever. Nothing is said about pain, so that we have no clue whether or not she had a stone, provided that we base the diagnosis of cholelithiasis on colicky pain in the right upper quadrant.

To go on with the physical examination, the only thing that is to be noted is that she was jaundiced and had an enlarged liver. We have nothing else

to help in the diagnosis. The hemoglobin was low, 8.5 gm., which is probably of significance. There is one statement regarding the urine that I do not believe is correct, "The urine was normal." I cannot conceive of a patient having a serum bilirubin of 15 mg. without some bile in the urine. It is possible that she had hemolytic jaundice, in which one does not see bile in the urine, but I doubt it.

I should also like to know whether a rectal examination and a proctoscopic examination were done. From a clinical point of view I cannot come to a conclusion without those examinations, especially in view of what the x-ray film of the colon showed.

DR. MOORE: Both were done. The rectal examination was negative, except for the fact that definitely gross blood was present. Proctoscopy was negative except for gross blood coming from above.

DR. LINTON: Have we the x-ray films? I do not know whether to look at them or not; they usually confuse me.

DR. LAURENCE L. ROBBINS: These are confusing; to say the least. I had considerable difficulty finding any films that demonstrated the lesion. So far as I can determine it is hidden in these loops of sigmoid, but on this spot film one can follow the rectum up to what is apparently the beginning of the sigmoid. Here one can see a definite shelf-like margin. On this spot film one can also see a shelf and what appears to be an area of ulceration in the center of the lesion. There is no evidence of polyposis.

DR. LINTON: I am really confused now. I had considered polyposis as a possibility because of the bleeding from the rectum. In view of the fact that neither proctoscopy nor the x-ray examination showed polyps, I must rule it out.

It seems to me that we have a patient who presented two conditions. I do not like to diagnose two conditions, and I should like to reason it out so that I can make one final diagnosis to explain the facts. This woman had obstructive jaundice and an ulcerating lesion in the rectosigmoid. I should like to know if a gastrointestinal series was done.

DR. BENJAMIN CASTLEMAN: It had been done at another hospital before she came here, and was said to be negative.

DR. LINTON: First of all, what conditions can produce jaundice in a patient who has had a cholecystectomy and a choledochostomy?

The first thing that enters my mind is the question whether she had developed stricture of the common duct secondary to the operation. That diagnosis, I believe, is a little unlikely because she was well for an interval of a year after the operation and seemed to have no evidence of jaundice during that period. It is unusual for a stricture to manifest itself a year after operation. If a patient has had damage done to the common duct, jaundice generally develops immediately or in a matter of a

weeks or months and persists rather than lets as happened in this patient. So I believe that can rule out stricture of the common duct as a cause of the recurrent jaundice.

Another possibility that one has to consider is carcinoma of the common bile duct. I believe that the history was too long for carcinoma of the bile duct. Malignant disease of the common duct usually obstructs the common duct early, and jaundice becomes pronounced in a short time — a matter of weeks.

Another possibility is carcinoma in the region of the ampulla, but I know of no way to be sure of such a diagnosis. I do not know whether one can pick up gallstones with a carcinoma in the region of the ampulla in the way that one can with a carcinoma of the gall bladder, which is practically always associated with gallstones. The fact that this patient had gallstones, and I presume that she had, makes me think that carcinoma in the region of the ampulla of Vater is a definite possibility. How are we going to explain such a diagnosis with the x-ray findings of a lesion in the rectosigmoid that is apparently malignant? Is that a justifiable conclusion?

DR. ROBBINS: Yes.

DR. LINTON: I am disturbed by the fact that the lesion was not seen on proctoscopic examination. Barium enemas of the rectosigmoid are not always accurate; but I should think that if the proctoscope had been passed its full length this lesion would have been visualized.

DR. CASTLEMAN: The first proctoscopic examination at the other hospital was unsatisfactory because there was too much fecal material. After she had been cleaned out, sigmoidoscopic examination was possible for only about 18 cm., where a right angle was encountered.

DR. MOORE: She was proctoscoped again here with the same unsatisfactory results.

DR. LINTON: Another possibility to explain the rectosigmoid lesion is a peritoneal implant from a carcinoma elsewhere in the intestinal tract that had deposited itself in the pelvis and had secondarily involved the rectosigmoid.

Another possibility that would explain the jaundice is carcinoma of the rectosigmoid with metastases to the liver. The patient had an enlarged liver, but the physical examination does not state whether it was nodular. I should expect it to have been nodular if it was so full of metastases to produce obstructive jaundice. Also, if it was due to metastatic disease, the metastases would have to be so local that they obstructed the common duct rather than the biliary radicals of the liver. I believe that is true because one can tie off 90 per cent of an animal's biliary system without its becoming jaundiced. It seems to me that, with the additional help from these statements about proctoscopy and

the barium enema, one cannot rule out the diagnosis of carcinoma of the rectosigmoid. I should be a little happier, however, if it had been felt by rectal examination or had been seen by proctoscopy. The only way that I can possibly connect the jaundice with such a lesion is to assume that metastases had localized around the common duct sufficiently to produce obstruction. I am therefore going to make a diagnosis of carcinoma of the rectosigmoid, with metastases to the liver in the region of the common duct and with obstruction of the latter.

DR. JOSEPH C. AUB: Does not the x-ray film show a colossal liver shadow pushing down the colon and shoving the stomach to one side?

DR. ROBBINS: I cannot be sure, but I doubt it.

DR. AUB: Does it not also show a big spleen?

DR. ROBBINS: There is slight enlargement of the spleen.

A PHYSICIAN: How does Dr. Linton explain the rectal bleeding eight years before entry?

DR. LINTON: I think that we have to explain it on the lesion in the rectosigmoid. It is possible to have a slowly growing lesion, although it is a little unusual.

DR. CASTLEMAN: If she had carcinoma, one can presuppose that it started as a polyp and later became malignant; of course, she also may have had hemorrhoids.

DR. AUB: If she had jaundice due to a neoplasm that disappeared and recurred, one has to assume that there was necrosis of the neoplasm, which relieved the tension and allowed bile to drain.

DR. CASTLEMAN: That happens with intraductal lesions but not with those exerting extrinsic pressure. For example, a tumor of the papilla of Vater often produces intermittent jaundice.

DR. MOORE: Dr. L. S. McKittrick operated on this patient, and his reasoning was much like that of Dr. Linton except that he thought the fact that the jaundice came and went was definite evidence against a neoplastic lesion in or about the common bile duct. Even taking into consideration the mechanism that Dr. Aub mentioned, it would still seem to be nonmalignant if it was capable of fluctuating.

CLINICAL DIAGNOSES

Stricture of common duct?

Carcinoma of sigmoid.

DR. LINTON'S DIAGNOSES

Carcinoma of sigmoid, with metastases to liver in region of common bile duct.

Obstructive jaundice.

ANATOMICAL DIAGNOSES

Stricture of common bile duct, traumatic, with biliary fistula.

Obstructive jaundice.

Adenocarcinoma of sigmoid.

PATHOLOGICAL DISCUSSION

DR. MOORE: At operation this patient was found to have had previous injury to the common duct that had completely destroyed 2 cm. of the duct. She had spontaneously formed a fistula in the scar tissue between the severed ends of the duct that let bile into the duodenum from time to time; the liver was enlarged because of the prolonged biliary obstruction but there was little evidence of biliary cirrhosis. In the midsigmoid was a sclerosing carcinoma.

DR. CASTLEMAN: At the first operation Dr. McKittrick repaired the common bile duct, using a vitallium tube, and at the second operation two weeks later, he resected the sigmoid and found what proved to be a slowly growing adenocarcinoma without metastasis to the regional nodes. The lesion itself was about 4 cm. in diameter and involved about half the circumference of the bowel.

It is surprising that the radiologists, both here and at the other hospital, had a difficult time finding the lesion in the sigmoid.

DR. ROBBINS: That is not hard to understand. In a markedly redundant sigmoid it is difficult to bring each loop into profile so that it can be seen in the fluoroscope. This is one of those cases, and it is surprising that the lesion was recognized at all.

DR. MOORE: The liver was not so big as it appeared in one of the x-ray films. It is deceiving, I suppose, because of the angle at which the film was taken.

DR. CASTLEMAN: Biopsy of the liver showed little parenchymal disease.

DR. LINTON: I still think it is rather unusual for a traumatic stricture of the common duct to manifest itself in this way.

DR. MOORE: It was not the usual type of traumatic stricture. A portion of the duct had been injured or destroyed at the previous operation. We were amazed that there was any bile in the duodenum. When we opened it and a probe was passed into the papilla, it proceeded 2 or 3 cm. and then came to a dead end. The duct was opened at that point, and 2 cm. was found to be missing before the hepatic duct was reached.

THE ORGANIZATION OF MEDICAL CARE

PHYSICIANS will do well to consider carefully the two papers appearing elsewhere in this issue of the *Journal* that deal with the place of the physician in the modern world. Dr. Kretschmer presents the orthodox views of those whose ideas have dominated organized medicine in this country; namely, that the marvelous achievements of American medicine spring from the freedom allowed the individual physician and that any fundamental change in the present system of medical practice will lead to regimentation and consequent stagnation. This point of view has been widely publicized through the editorial columns of the *Journal of the American Medical Association* and the literature distributed

by the National Physicians' Committee. The essence of the argument of this group is that the organization of medical care is the concern of the medical profession alone. Most physicians are familiar with the argument, and many agree with it. Nevertheless, there are other points of view, both within the profession and among the hundred and thirty million Americans who, as patients, have a very direct interest in both the quality and the cost of medical care. In considering any problem, it is always well to view it in historical perspective, and for doctors particularly it may be worth while to examine objectively the place of their profession as it appears to a member of another profession — the law — that attempts to train its practitioners to take a broad and dispassionate view of human society. For these reasons, the paper by Mr. Berge should be read and pondered — but not necessarily agreed with — before anyone arrays himself in the ranks of those who champion the rights of the individual physician as the sole arbiter of systems of medical practice.

Certain facts appear to be inescapable. First, the cost of medical care, including payment for professional service, drugs and hospitalization, constitutes a considerable portion of our national expenses; second, the costs of illness, striking the individual unexpectedly, frequently exceed his capacity to pay at that particular time; third, it is possible to insure against such risks; and, finally, more and more people are beginning to consider good medical and hospital care and adequate health protection as essential. There can be little dispute about these facts; even the National Physicians' Committee has come to the conclusion that the public wants prepaid medical care, and Dr. Kretschmer states that the medical profession "is keenly aware of the importance of increasing the distribution of good medical service to all the people."

The dispute rages not so much over what is needed as on how to achieve it. Many plans are in the air, ranging from the far-reaching provisions of the Wagner-Murray-Dingell Bill in this country and the plan for a national health service as outlined by the White Paper¹ in Britain to individual agreements between physicians and their patients to provide professional service on an annual-payment

basis. Massachusetts has been one of the states in which there has been a lot of interest in finding a way to solve the problem of the distribution of medical care more equitably both for the patient and for the doctor. The White Cross Plan, sponsored as an experiment along these lines, aroused a great deal of comment, and subsequently the Massachusetts Medical Society launched the Blue Shield Plan. It is to be hoped that the latter, which admittedly gives only partial coverage at present, will continue to evolve until far more adequate service is provided.

Basically, there are two problems with which both the public and the medical and allied professions are concerned: that of paying for medical care and that of assuring the highest quality of medical care for the most people. The first is purely an economic problem, and almost any solution is bound to benefit both the public, which bears the costs, and the physicians, nurses, hospitals and other non-tax-supported groups that provide medical service, much of it on a partial or complete charity basis. The second problem has economic, political and technologic aspects. Its technologic phase is obviously the sole concern of the medical profession, which alone has the knowledge on which to base judgments of the quality of professional service or to institute improvements in the care of patients, in institutional standards or in the training of physicians. The public, however, has a direct concern in seeing to it that advances in medicine are made available as rapidly and as widely as possible. Here is the chief source of friction, since, in order to achieve the double objective of distributing the costs of medical care most equitably and of providing the best quality of medical service to the largest number of persons, governmental intervention at either the local or the federal level is contemplated. One group believes, with some justification, that the quality of medical service available to the country as a whole is inadequate compared with what it ought to be, both as regards hospital and laboratory facilities and the professional competence of those who utilize them. The other group contends, also with some justification, that facilities may not be ideal but are adequate in most portions of the United States, that these are being constantly

improved by organized medicine and that any advantage gained temporarily in the improvement of professional standards made possible by a federal scheme would soon be lost in the inevitable political regimentation that would result.

These are matters with which every physician should be concerned both as a citizen and as a doctor. The inertia of the bulk of the profession, combined with an opposition to change on the part of medical organizations, has led to a situation in which public opinion has forced the hand of the medical profession. Now the inevitability of some change is generally accepted. It is to be hoped that more local experimentation with different plans will be possible before a national health program is organized, so that the latter can be based on knowledge gained through experience. Those who wish to keep themselves informed on developments in this field should follow the reports published in the "Organization Section" of the *Journal of the American Medical Association* and should read the British White Paper, the text of the Murray-Wagner-Dingell Bill and a report to be published² that summarizes the ideas of those who have been particularly concerned with the development of a national health program. This is a field that should be approached with the same objectivity and detachment as a scientific experiment, so that the profession may make real contributions toward the solution of a problem with which both physicians and the general public are deeply concerned.

MASSACHUSETTS MEDICAL SOCIETY COMMITTEE ON MEDICAL INFORMATION BUREAU

The appended statement has recently been forwarded to the secretaries of all district medical societies of the Massachusetts Medical Society, as well as to various hospitals.

WALTER G. PHIPPEN, *Chairman*
* * *

The Massachusetts Medical Society has established the Bureau of Clinical Information at its headquarters, 8 Fenway, Boston, as a means of augmenting its postgraduate educational effort.

The Bureau will supply information concerning the daily activities of the approved hospitals in Boston and its immediate vicinity. This information will deal with each hospital's daily schedule of operations, medical and surgical rounds and clinics, including the names of those pre-acting over these various activities and the location of the clinics. From time to time the Bureau will make available a bulletin that will list the fixed medical meetings and conferences held in the metropolitan area. This will be sent to hospitals, medical schools and physicians on request, and will be available at the Bureau. In brief, the ultimate aim of the Bureau is to serve the profession as a clearinghouse for all sorts of medical information.

The Bureau will be open from 7:00 a.m. to 10:00 a.m. and from 3:00 p.m. to 8:00 p.m., except Saturday afternoons. Information will be given by telephone.

You are requested to acquaint the physicians of your area with this new activity. No expense is involved on the part of those using this service.

ARTHUR W. ALLEN, M.D.

MICHAEL A. TIGHE, M.D.

WALTER G. PHIPPEN, M.D., *Chairman*

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

CHANGES IN ISOLATION AND QUARANTINE REQUIREMENTS

A new printing of the isolation and quarantine requirements of the Massachusetts Department of Public Health, embodying recent changes, is now ready for distribution. Copies may be obtained by writing to the department.

Since the last revision, in 1941, three additional diseases (chancroid, granuloma inguinale and lymphogranuloma venereum) have been added to the reportable list and several changes in the previous regulations have been made. The major changes are as follows:

REGULATIONS

Chancroid. Column 1, placed in table immediately after "Asiatic cholera." Column 2, "No restrictions if under continuous treatment." Column 3, "No restrictions if examination demonstrates absence of infection." Columns 4 and 5, "Same as for adults." Column 6, "No."

German measles. Column 2, amended to read, "Three days from appearance of rash."

Gonorrhea. Column 2, omitted "See 'Regulations Governing the Control of Gonorrhea and Syphilis'" and substituted "No restrictions if under continuous treatment." Column 3, "No restrictions if examination demonstrates absence of infection." Columns 4 and 5, "Same as for adults." Column 6, "No."

Granuloma inguinale. Column 1, placed in table immediately after "Gonorrhea." Column 2, "No restrictions if under continuous treatment." Column 3, "No restrictions if examination demonstrates absence of infection." Columns 4 and 5, "Same as for adults." Column 6, "No."

Lymphogranuloma venereum. Column 1, placed in table immediately after "Lymphocytic choriomeningitis." Column 2, "No restrictions if under continuous treatment." Column 3, "No restrictions if examination demonstrates absence of infection." Columns 4 and 5, "Same as for adults." Column 6, "No."

Measles. Column 3, omitted "Note 1" and substituted "No restrictions." Column 5, amended to read "No restrictions."

Meningitis, meningococcal. Column 2, amended to read, "Two weeks from onset of disease (five days in cases adequately treated with sulfonamide drugs), and thereafter until all acute symptoms have subsided."

Meningitis, other forms, such as Pfeiffer bacillus, pneumococcal, streptococcal, etc. Column 1, order of words changed

to read "Meningitis: Pfeiffer bacillus, pneumococcal, streptococcal and other forms."

Scarlet fever. Column 2, amended to read: "Uncomplicated cases: Adults, two weeks; children, three weeks from date of appearance of rash. Examine nose, throat and ears to detect existence of discharge or inflammation before considering case as uncomplicated. (If upper respiratory tract symptoms appear during month after release from isolation, re-establish precautions.) Complicated cases: Four weeks and thereafter until abnormal discharge shall have ceased, swollen glands subsided or three successive cultures of abnormal discharge shall have been found free of hemolytic streptococci." Column 3, amended to read, "No restrictions except for milk handlers and schoolteachers who may continue their occupation only with special permission of the local board of health." Column 5, amended to read: "Until child lives away from home one week; no restrictions thereafter, if child continues to live away from home. Quarantined contacts living in a household with a case should be allowed to return to school at the same time as the patient is released from isolation."

Syphilis. Column 2, omitted "See 'Regulations Governing the Control of Gonorrhea and Syphilis'" and substituted "No restrictions if under continuous treatment, except as given in Note 5." Column 3, "No restrictions if examination demonstrates absence of infection." Columns 4 and 5, "Same as for adults." Column 6, "No."

Whooping cough. Column 3, omitted "Note 1" and substituted "No restrictions."

NOTES

Note 1. Incorporated in new Note 2. New Note 1 reads, "Definition of adult: Any person who has reached his eighteenth birthday is considered to be an adult for purposes of these regulations."

Note 2. Now includes old Note 1.

Note 4. Omitted entirely; substituted Note 5, renumbered.

Note 5. Changed to Note 4; substituted "Patients who have lesions of primary or secondary syphilis on exposed parts of the body or in the mouth, and are employed in any occupation requiring regular, direct contact with other persons, such as barber, hairdresser, manicurist, waiter, waitress, nursemaid, domestic, etc., shall be reported by name, address and occupation to the State Department of Public Health, unless the physician will assume responsibility for seeing that the patient discontinues such occupation until the lesions are healed."

Note 8. Omitted entirely; substituted "All of the above diseases except five should be reported to the local board of health. The five exceptions (chancroid, gonorrhea, granuloma inguinale, lymphogranuloma venereum and syphilis) should be reported directly to the State Department of Public Health on special forms, provided upon request."

IMMUNE SERUM GLOBULIN FOR MEASLES

For the past two and a half years the Division of Biologic Laboratories of the Department of Public Health has been collaborating with the Department of Physical Chemistry of the Harvard Medical School (under contract with the Office of Scientific Research and Development), the American Red Cross, the Bureau of Medicine and Surgery of the United States Navy and associated clinical and other groups in the development and use of a purified antibody fraction from human plasma. This study followed the successful purification of human serum albumin by a process developed under the same sponsorship and collaborative efforts. A number of physicians in Massachusetts have become familiar with this antibody fraction, known officially as "Immune Serum Globulin" (but known to many by the chemist's name "gamma globulin") through the preparations distributed to them from

basis. Massachusetts has been one of the states in which there has been a lot of interest in finding a way to solve the problem of the distribution of medical care more equitably both for the patient and for the doctor. The White Cross Plan, sponsored as an experiment along these lines, aroused a great deal of comment, and subsequently the Massachusetts Medical Society launched the Blue Shield Plan. It is to be hoped that the latter, which admittedly gives only partial coverage at present, will continue to evolve until far more adequate service is provided.

Basically, there are two problems with which both the public and the medical and allied professions are concerned: that of paying for medical care and that of assuring the highest quality of medical care for the most people. The first is purely an economic problem, and almost any solution is bound to benefit both the public, which bears the costs, and the physicians, nurses, hospitals and other non-tax-supported groups that provide medical service, much of it on a partial or complete charity basis. The second problem has economic, political and technologic aspects. Its technologic phase is obviously the sole concern of the medical profession, which alone has the knowledge on which to base judgments of the quality of professional service or to institute improvements in the care of patients, in institutional standards or in the training of physicians. The public, however, has a direct concern in seeing to it that advances in medicine are made available as rapidly and as widely as possible. Here is the chief source of friction, since, in order to achieve the double objective of distributing the costs of medical care most equitably and of providing the best quality of medical service to the largest number of persons, governmental intervention at either the local or the federal level is contemplated. One group believes, with some justification, that the quality of medical service available to the country as a whole is inadequate compared with what it ought to be, both as regards hospital and laboratory facilities and the professional competence of those who utilize them. The other group contends, also with some justification, that facilities may not be ideal but are adequate in most portions of the United States, that these are being constantly

improved by organized medicine and that any advantage gained temporarily in the improvement of professional standards made possible by a federal scheme would soon be lost in the inevitable political regimentation that would result.

These are matters with which every physician should be concerned both as a citizen and as a doctor. The inertia of the bulk of the profession, combined with an opposition to change on the part of medical organizations, has led to a situation in which public opinion has forced the hand of the medical profession. Now the inevitability of some change is generally accepted. It is to be hoped that more local experimentation with different plans will be possible before a national health program is organized, so that the latter can be based on knowledge gained through experience. Those who wish to keep themselves informed on developments in this field should follow the reports published in the "Organization Section" of the *Journal of the American Medical Association* and should read the British White Paper, the text of the Murray-Wagner-Dingell Bill and a report to be published² that summarizes the ideas of those who have been particularly concerned with the development of a national health program. This is a field that should be approached with the same objectivity and detachment as a scientific experiment, so that the profession may make real contributions toward the solution of a problem with which both physicians and the general public are deeply concerned.

MISCELLANY

ATYPICAL PNEUMONIA SIMULATING PULMONARY TUBERCULOSIS

A new disease of the respiratory tract has captured a place on the medical scene during the past decade. Primary atypical pneumonia — to give it the name that seems most commonly used — has probably existed for years masquerading as atypical influenza or gripe. With the increasing use of x-ray films in diagnosis the prevalence of the disease has begun to emerge, and its importance to be recognized. The danger would now appear to be that it is as yet incompletely differentiated from pulmonary tuberculosis and that, unless progress film studies are carried out, some cases of tuberculosis will be treated for pneumonia and some cases of pneumonia given tuberculosis therapy. The following is an abstract of a paper (Yoskalka, J. S. A typical pneumonia simulating pulmonary tuberculosis. *Am. Rev. Tuberc.* 49:408-413, 1944) that considers this problem.

For many years it has been the teaching of the medical profession to regard a patient subacutely ill with infiltrations of the upper lung fields in x-ray films as probably tuberculous unless proved otherwise. Recently it has become apparent that atypical pneumonia can produce lesions that at times are indistinguishable from pulmonary tuberculosis. This has been reported on several occasions. With the apparent increase in the incidence of atypical pneumonia, especially since the profession is becoming more conscious of it, it is evident that criteria for a differential diagnosis of these two conditions should be formulated.

Clinical Observations

The symptoms and clinical signs of atypical pneumonia have been adequately described in the current literature. The usual gradual onset of the disease, associated with malaise, generalized aches and pains, dry, nonproductive cough and fever may be simulated by any case of acute pneumonic tuberculosis. A differential diagnosis cannot be made solely on the basis of the history and physical examination. Where serial roentgenograms are not feasible, the persistence of cough and expectoration, together with the finding of rales for a period greater than twenty-one days from the onset of the disease, should lead one to suspect tuberculosis, even though the patient appears to be much improved.

Röntgenologic Aspects

In our 7 cases of upper-lobe atypical pneumonia two types of shadows were found on the films. The most frequent was an increase in the bronchial markings manifested by linear streaking densities with superimposed mottled shadows. This was most marked at the hilum and, with an extension of the disease, spread toward the periphery of the lung fields. The other type of finding was an area of increased tissue density in the parenchyma of the lung relatively uniform throughout and resembling the shadow seen in early pleural effusion. X-ray evidence of atelectasis was found in our cases only when the entire right upper lobe was involved. Complete involvement of an upper lobe will usually reveal some associated evidence of atelectasis, whereas in complete consolidation of a lobe due to pneumonic tuberculosis this is usually not the case. Because there was such a wide divergence of roentgenologic findings in our cases of atypical pneumonia it was thought that we could not make a definite differential diagnosis from a single film. In serial x-ray studies it was observed that cases of atypical pneumonia could be expected to show complete clearing of the chest involvement in from four to twenty days. If the serial roentgenograms still reveal a density twenty days after the onset of the illness, pulmonary tuberculosis must be seriously considered even if other evidence favors an x-ray diagnosis of atypical pneumonia.

Case Reports

CASE 1. A white soldier was admitted to hospital with a 1-day history of generalized aches and pains, headache, malaise, fever and chilly sensations. The physical findings were normal except for a moderate injection of the pharynx; the temperature was 100°F., the pulse rate 82, and the respirations 20 per minute. The white-blood-cell count was 9200, with 72 per cent polymorphonuclears. The working diagnosis was influenza. The patient continued to run a fever reaching 103.8°F. 2 days later. Within 4 days he had developed a nonproductive cough. Physical examination at that time revealed suppressed breath sounds with an occasional fine moist rale in the right upper lobe. An x-ray film of the chest showed complete consolidation of the right upper lobe. This had almost completely cleared within a week's time, although the fever persisted somewhat longer. Recovery was uneventful and the patient was discharged to duty on the 20th hospital day.

Comment. This case illustrates the difficulty of making a definite diagnosis roentgenologically. Bacteriologic examinations were negative, and the rapid clearing of the lesion ruled out tuberculosis.

CASE 2. A white soldier was admitted to the hospital with a 2-day history similar to that above. The admission temperature was 101°F., the pulse rate 100, and the respirations 20 per minute. The white-blood-cell count was 6800 with 64 per cent polymorphonuclears. The working diagnosis was influenza. A film of the chest made 4 days following the onset of the illness showed marked increase in the hilar shadow with marked mottled densities throughout the right upper lobe. In one area there was a shadow with a central high light suggestive of cavitation. The film made 15 days following onset showed complete clearing of the parenchymal lesions.

Because of the x-ray film suggesting cavitation, sputum and gastric studies were made. All were found to be negative for tubercle bacilli. The patient made an uneventful recovery and was discharged on the 22nd hospital day.

the Children's Hospital, Boston, or the Division of Biologic Laboratories for study purposes.

The superiority of immune serum globulin for the control of measles has been well demonstrated, and the department has been looking forward to the time when this material would become available for general use. Once the proof of its usefulness had been established, the availability of immune serum globulin depended on the accumulation of sufficient reserves to take care of any possible needs of the armed forces. Such reserves are now on hand. The globulin is derived from blood donated by volunteers through the American Red Cross for the armed forces, and the Red Cross has made arrangements for the distribution of the surplus for civilian use as long as it is available (*J. A. M. A.* 125:638, 1944). Material so distributed will be processed at cost by the commercial firms now preparing albumin for the armed forces, and will be furnished without charge to the public through state health departments or related organizations, which will bear the expense of processing and distribution. In Massachusetts the globulin is available through this department, and distribution will begin on December 1. The immune serum globulin will in every respect take the place of immune globulin (placental extract), which the department has distributed for the past ten years as an agent for the control of measles. The distribution of placental extract has therefore been discontinued. Sodium citrate solution, which has been used as an anticoagulant in the administration of parental blood for the control of measles, is also being discontinued.

Immune serum globulin is used in the same fashion as placental extract and with the same indications, that is, for the modification of measles in an exposed healthy susceptible person three years of age or older and for the prevention of measles in exposed infants under three years of age, debilitated or chronically or acutely ill older patients or groups of susceptibles in whom a measles epidemic must be avoided.

The attention of physicians is called to the fact that the globulin is most effective when given to a freshly exposed person during the first six days after the date of exposure, although some effect may be at times obtained if it is given as late as the tenth day. The globulin does not permanently immunize a child to measles: although complete immediate protection is usually obtained to exposure, the child again becomes susceptible in three or four weeks. If, on the other hand, modified or unmodified measles occurs, permanent immunity is usually conferred by the attack. Detailed directions for use of the immune serum globulin are included in each package.

The globulin will be distributed through the usual channels — to local boards of health having approved biologic depots or directly to physicians, hospitals or other institutions unable to obtain their

needs through their local boards of health. Physicians and others obtaining supplies of this material are urgently requested to keep their orders within their probable needs for a period of two or three weeks. Since the Department has to purchase globulin, the supply is limited, and it is hoped that the available supply be distributed as equitably as possible.

COMMUNICABLE DISEASES IN MASSACHUSETTS FOR OCTOBER, 1944

COMMENT

No unusual trends are indicated by the figures for October. The usual seasonal increase of several of the diseases has not as yet become marked enough to indicate which are likely to be high during the coming year. Measles and scarlet fever are unusually low because of the downward swing after two years of high prevalence.

Poliomyelitis during October, although still much above the seven-year median, showed a marked decrease from the August and September prevalence. The usual seasonal drop to a very low level may be expected in succeeding months.

Meningococcus meningitis continues to run well below last year's level, although still above the seven-year median. The same is true, to a lesser degree, of scarlet fever.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from: Amherst, 1; Arlington, 2; Barre, 2; Beverly, 1; Boston, 16; Boylston, 1; Brockton, 2; Brookline, 1; Cambridge, 1; Chelsea, 1; Chicopee, 6; Dedham, 1; Everett, 1; Fitchburg, 1; Framingham, 2; Greenfield, 1; Hancock, 1; Hanover, 1; Haverhill, 1; Hingham, 2; Lee, 1; Ludlow, 2; Lynn, 1; Medford, 1; Natick, 2; Newburyport, 1; Newton, 6; Orange, 1; Pepperell, 1; Pittsfield, 15; Reading, 3; Revere, 2; Somerville, 1; Springfield, 1; Stockbridge, 1; Swampscott, 1; Waltham, 1; Watertown, 2; Webster, 1; Weymouth, 2; West Brookfield, 1; West Stockbridge, 1; Worcester, 6; total, 99.

Diphtheria was reported from: Boston, 3; Cambridge, 2; Everett, 1; Lowell, 5; Somerville, 7; Worcester, 1; total, 19.

Dysentery, bacillary, was reported from: Billerica, 1; Boston, 4; Fall River, 6; Lexington, 8; Lowell, 1; Malden, 5; Medford, 2; Peabody, 1; Plainville, 2; Somerville, 1; Stoneham, 1; total, 32.

Encephalitis, infectious, was reported from: Springfield, 1; total, 1.

Malaria was reported from: Boston, 1; Cambridge, 2; Camp Edwards, 4; Chelsea, 2; Chicopee, 1; Cushing General Hospital, 20; Lowell, 1; Peabody, 1; Revere, 1; Somerville, 1; Waltham, 2; total, 36.

depressing metabolism and allaying fear. Unfortunately, in doses large enough to produce amnesia it frequently causes respiratory depression. By the addition of scopolamine in doses as low as 1/200 gr.) the patient can frequently be rendered amnesic for the period immediately before the trip to the operating room and for his stay there. Scopolamine has the effect of producing a "don't care" state of mind even though the patient may be quite alert. Furthermore, scopolamine is as effective as, if not superior to, atropine in inhibiting secretions from the mucous membranes. Since this drug does not cause respiratory depression in therapeutic doses, it is an excellent adjuvant to morphine for preoperative medication. The addition of small doses of a barbituric acid derivative (2 gr. of Sodium Luminal in the case mentioned) frequently helps to render the patient unconscious during the operative procedure.

In the editorial it is stated that fifteen minutes after the administration of the anesthetic agent, the anesthetist was busy giving artificial respiration and the nurse was giving coramine subcutaneously. It is hard to understand how this respiratory difficulty could have been due to the preoperative sedation with the patient breathing twelve to fifteen times a minute after what was probably a brief operative procedure. It would also seem that a drug depression serious enough to require artificial respiration would have been noted before the anesthetic was given.

From the small amount of information given in the article it seems a much likelier conclusion that the spinal anesthetic agent had progressed far enough cephalad to paralyze some or all of the intercostal muscles or even the diaphragm, and by the time the operation was completed, this paralysis had worn off sufficiently to permit spontaneous respiration. If this conclusion is correct, the administration of the coramine was superfluous, since the only effective treatment for this condition is artificial respiration after the establishment of an adequate airway.

The proportions of the various drugs used for preoperative sedation have been arrived at after very careful pharmacologic and clinical research. It is quite obvious that the ideal dose cannot always be selected and that there will always be some patients in whom the effect produced by the preoperative sedation will be too profound, as well as some for whom the ordered dose will be insufficient. Fortunately, in the hands of experienced anesthesiologists who are able to recognize quickly the signs of undersedation and oversedation, as well as the effects of spinal anesthetics that have gone too high, the ill effects of these inadvertent administrations can be taken care of without danger to the patient or impairment of the surgeon's work.

It is to be hoped that the opinion expressed by the author of the editorial in question does not represent the consensus of a large group of surgeons. I am sure that such an attitude can but tend to reflect discredit on an important medical specialty, and indirectly be disadvantageous to patients undergoing surgical procedures.

URBAN H. EVERSOLE, M.D., *Director*
Department of Anesthesia

Lahey Clinic
Boston

To the Editor: It is the opinion of the undersigned that several of the statements and implications made in the editorial entitled "Polypharmacy and Anesthesia" appearing in the August 3 issue of the *Journal* are misleading.

The writer of that editorial "wonders how the anesthetist knows that 1/200 gr. of scopolamine is going to contribute to the success of the anesthesia." He further states that the anesthetist should "limit himself to a moderate dose of a sedative, together with a suitable dose of atropine or some substance having the pharmacologic effect of atropine."

A little reading in preparation for the editorial would have disclosed that scopolamine is a valuable sedative and that it effectively counteracts the respiratory depressant action of morphine if given in proper dosage. A short perusal of a text on pharmacology would have revealed that scopolamine in fact does have many of the valuable pharmacologic effects of atropine.

The fact that Sodium Luminal was given is lightly glossed over by the writer of the editorial. Long-acting barbiturates are usually not indicated as preanesthetic drugs.

The writer of the editorial, if he were at all familiar with anesthetic practices, would have been more concerned with

the action of spinal anesthesia in producing respiratory paralysis in this case rather than with attacking so strongly the preanesthetic drugs.

The use of coramine and carbon dioxide in the treatment of the respiratory depression as described is open to criticism.

The fact that satisfactory tidal exchange was established and maintained is a credit to the anesthetist.

The statement is made that when nurse technicians are employed to administer the anesthesia, heavy premedication is avoided because the surgeon gives the orders. This may be the experience of the one who wrote the article, but it is by no means universal.

The editorial recommends that the surgeon, in order to protect his patient, consult with the anesthesiologist in detail concerning each step of medication given before, during and after operation. It is certainly to be hoped that the surgeon will consult with the anesthesiologist in detail about each patient about to undergo anesthesia and surgery. For the better and fuller protection of the patient, I suggest that the surgeon choose a thoroughly qualified anesthetist and depend on the anesthesiologist's more thorough knowledge of sedatives to safeguard the patient against accidents. There is no clinician more familiar with the pharmacologic action of narcotics and hypnotics than the anesthesiologist.

It is stated that in the present state of anesthesia, there is too much art and not enough science. With this statement I take strong issue. An increase in the art and a tempering of the science of anesthesia would elevate the present status of this practice.

MEYER SAKLAD, M.D.
Director of Anesthesia

Rhode Island Hospital
Providence 2, Rhode Island

The above letters are typical of many that have been received from anesthesiologists in criticism of the editorial "Polypharmacy and Anesthesia." The editorial presented an abbreviated case report, and from the events described therein, it was deduced that the premedication was chiefly responsible for the alarming symptoms. It was assumed that the slow shallow respirations subsequent to the period of apnea were caused by this medication. This interpretation is questioned by expert pharmacologic opinion, and it appears likelier that the apnea and the depressed respirations were the result of a spinal anesthesia that had progressed too high. For this, the *Journal* humbly apologizes.

Nevertheless, it should still be pointed out that there is a large body of medical opinion, found perhaps more among surgeons than among anesthetists, that simplification of premedication is a goal to be sought in future advances in anesthesia. Although the excellent human experimental work of Waters and his associates referred to in the letter from the group of Boston anesthetists has indicated that combinations of morphine and scopolamine and of Pentobarbital Sodium and scopolamine are useful and, in moderate doses, safe, there are no similar studies in which the triple combination of morphine, scopolamine and a barbiturate has been given. In fact, as indicated by Dr. Saklad's letter, some anesthetists do not approve a combination of a long-acting barbiturate and morphine in premedication.

The discussion evoked by the editorial can do nothing but good. If it can be followed up by additional experimental work and by careful observation and analysis of large numbers of cases, it may be possible to work out a universally acceptable simple form of premedication for the less intricate operative procedures in healthy patients. — Ep.

BOOK REVIEWS

The Permeability of Natural Membranes. By Hugh Davson, D.Sc.; and James F. Danielli, D.Sc., A.I.C. With a foreword by E. Newton Harvey, Ph.D. 8°. cloth, 361 pp., with 73 illustrations and 72 tables. New York: The Macmillan Company, 1945. \$4.75.

The great usefulness of this book will be obvious to all students of biology. The authors present a general survey of the field of permeability, including materials essential for students of medicine, physiology, biochemistry, zoology and botany. It is made clear that permeability studies have passed beyond the preliminary exploratory stage, having

CASE 3. A white soldier was admitted to the hospital with a history and physical findings similar to Cases 1 and 2. The working diagnosis was atypical pneumonia of the right upper lobe. This was confirmed by roentgenogram. The patient had a low-grade fever for 8 days following admission. A roentgenogram taken on the 11th hospital day showed some clearing of the pneumonic process. Since the persistence of physical signs in the chest and the slow clearing of the chest lesion despite clinical improvement of the patient are not usual in atypical pneumonia, sputum examinations were begun. Tubercle bacilli were found. This was confirmed in later examinations of the sputum.

Summary

Atypical pneumonia may simulate pulmonary tuberculosis both clinically and roentgenographically, and the reverse is equally true.

Approximately 7 to 10 per cent of atypical pneumonias have upper-lobe involvement, which is the usual site for pulmonary tuberculosis.

Serial roentgenograms showing apical lesions failing to clear in twenty days following the onset of the disease should raise the suspicion of pulmonary tuberculosis.

Sputum studies for tubercle bacilli are indicated in all doubtful cases.

If lesions persist for twenty days from the onset of the illness, and routine sputum studies are negative, further studies should be done, that is, sputum and gastric concentrates and guinea-pig inoculation.

Because of the apparent increase in the incidence of atypical pneumonia, the need for an early differential diagnosis is imperative. — Reprinted from *Tuberculosis Abstracts* (November, 1944).

CORRESPONDENCE

"POLYPHARMACY AND ANESTHESIA"

To the Editor: In the August 3 issue of the *Journal* there appeared an editorial entitled "Polypharmacy and Anesthesia" which seems to call for some reply from those of us practising as specialists in anesthesiology. A case is cited in which preliminary to procaine-pontocaine spinal anesthesia for appendectomy in "a healthy, seventeen-year-old boy" premedication of "1/6 gr. of morphine, 1/200 gr. of scopolamine and 2 gr. of Sodium Luminal" was given "by injection." Information is lacking as to the intervals before induction of anesthesia at which these drugs were administered, as is any statement about the dosage of procaine and pontocaine or the spinal level attained by the subarachnoid block. Respiratory depression or failure supervened fifteen minutes after induction of anesthesia, and was ascribed by the writer of the editorial to the preliminary medication. Although it seems much more likely, on the basis of the account, that the respiratory difficulty was caused chiefly if not entirely by the ascent of the spinal drugs to a high level, and not by the medication, pharmacologic questions are raised that should be answered. "One wonders how the anesthetist knows that 1/200 gr. of scopolamine is going to contribute to the success of this procedure. Would not 1/4 gr. or even 1/2 gr. of morphine achieve approximately the same effect? One also wonders, but not so seriously, whether the Sodium Luminal was necessary?"

To answer these queries in order: The anesthesiologist knows from his clinical experience and from his knowledge of pharmacology that 1/200 gr. of scopolamine will probably contribute to the success of spinal anesthesia. One quarter or one third of a grain of morphine would not achieve approximately the same effect, because the pharmacologic effects of morphine differ fundamentally from those of scopolamine. It could be said that the Sodium Luminal (phenobarbital) is not absolutely necessary, but it contributes to the comfort and safety of the patient.

The combination and dosage of the three drugs mentioned, far from being "a practically fatal combination of sedatives," is commonly prescribed by anesthesiologists and is well within the limits of safety. Each is employed for a definite purpose. The barbiturate, in addition to its soporific effect, protects against possible toxic reaction to the local anesthetic drugs. Goodman and Gilman¹ state: "Soporific doses of the

barbiturates are only slightly depressant to the respiration; [while] morphine is a primary and continuous depressant of respiration by virtue of a direct action on the respiratory center. The effect is discernible with small doses insufficient to produce sleep or disturb consciousness. The action is a highly selective one, and the depression is directly proportional to the dose."

Sedation produced by the combination of the two drugs in moderate dosage results in less respiratory depression than would result from a large dose of morphine alone.

Scopolamine, although apparently considered by the writer of the editorial as a sedative, in reality belongs to the atropine group of drugs. We again quote Goodman and Gilman:² "Scopolamine, like atropine, has a potent inhibitory action on secretions, but in addition, the alkaloid is also a depressant of the central nervous system and reduces excitement. Scopolamine is often viewed as a respiratory depressant, but this action on the medullary center has been exaggerated. Indeed strong evidence from clinical experiments of Waters and his associates² indicates that the depression of breathing by morphine can be completely counteracted by doses of scopolamine, so that otherwise poisonous amounts of morphine may be administered to man without lowering the normal respiratory exchange."

It appears unprofitable to discuss the opinions expressed in the latter part of the editorial. We hope that the opening paragraph better reflects the beliefs of the majority of members of the medical profession: "The scientific advances in anesthesia in the last decade have been truly spectacular, and largely because of them, surgeons have been able to operate successfully in many regions of the body previously inaccessible. Furthermore, the safety of other operative procedures has been increased by these new methods, provided they are expertly applied."

2. Waters, R. M. Study of morphine, scopolamine and atropine and their relation to preoperative medication and pain relief. *Texas State J. Med.* 34:304, 1938.

To the Editor: The editorial "Polypharmacy and Anesthesia," which appeared in the August 3 issue of the *Journal*, contains so many statements at variance with commonly accepted opinions concerning preoperative sedation that it seems wise to call them to your attention. In addition to the somewhat obvious inaccuracies in this article, the entire tone of the editorial is such as to reflect on an important medical specialty.

The editorialist seemed most concerned about what he considered to be too much preoperative sedation administered to a certain patient. One-sixth grain of morphine, 1/200 gr. of scopolamine and 2 gr. of Sodium Luminal could not be considered heavy medication for a healthy, seventeen-year-old male patient. It seems that the scopolamine was the drug considered to be the offender.

Since the editorial betrayed little appreciation of the purpose of preoperative medication and the action of the respective drugs used, a few words on the subject appear appropriate. The ideal premedication should allay the patient's fears of the operating room and produce a state of relative amnesia for the period. Furthermore, if an inhalation anesthetic is to be used (and this sometimes has to be resorted to even when not planned), the preoperative medication should lower the metabolic rate in order to facilitate induction and lessen the amount of anesthetic agent required to obtain the desired level of anesthesia. The preoperative medication should do all of this without sufficiently depressing respiration as to slow the absorption of the anesthetic agent and of oxygen or to predispose to postoperative pulmonary complications because of this depressed respiration and obtunded cough reflex. Morphine is an excellent drug

depressing metabolism and allaying fear. Unfortunately, in doses large enough to produce amnesia it frequently causes respiratory depression. By the addition of scopolamine doses as low as 1/200 gr.) the patient can frequently be rendered amnesic for the period immediately before the trip to the operating room and for his stay there. Scopolamine the effect of producing a "don't care" state of mind even though the patient may be quite alert. Furthermore, scopolamine is as effective as, if not superior to, atropine in inhibiting secretions from the mucous membranes. Since this drug does not cause respiratory depression in therapeutic doses, it is an excellent adjuvant to morphine for pre-anesthetic medication. The addition of small doses of a barbituric acid derivative (2 gr. of Sodium Luminal in the case mentioned) frequently helps to render the patient unconscious during the operative procedure.

In the editorial it is stated that fifteen minutes after the administration of the anesthetic agent, the anesthetist was giving artificial respiration and the nurse was giving amine subcutaneously. It is hard to understand how this respiratory difficulty could have been due to the preoperative atropine with the patient breathing twelve to fifteen times a minute after what was probably a brief operative procedure. It would also seem that a drug depression serious enough to require artificial respiration would have been noted before the anesthetic was given.

From the small amount of information given in the article seems a much likelier conclusion that the spinal anesthetic agent had progressed far enough cephalad to paralyze some of all of the intercostal muscles or even the diaphragm, and at the time the operation was completed, this paralysis had worn off sufficiently to permit spontaneous respiration. If this conclusion is correct, the administration of the coramine is superfluous, since the only effective treatment for this condition is artificial respiration after the establishment of an adequate airway.

The proportions of the various drugs used for preoperative anesthesia have been arrived at after very careful pharmacologic and clinical research. It is quite obvious that the ideal dose is not always to be selected and that there will always be some patients in whom the effect produced by the preoperative atropine will be too profound, as well as some for whom the desired dose will be insufficient. Fortunately, in the hands of experienced anesthesiologists who are able to recognize quickly the signs of underdosage and overdosage, as well as the effects of spinal anesthetics that have gone too high, the ill effects of these inadvertent administrations can be taken care of without danger to the patient or impairment of the surgeon's work.

It is to be hoped that the opinion expressed by the author in the editorial in question does not represent the consensus of a large group of surgeons. I am sure that such an attitude will tend to reflect discredit on an important medical specialty, and indirectly be disadvantageous to patients undergoing surgical procedures.

To the Editor: It is the opinion of the undersigned that several of the statements and implications made in the editorial entitled "Polypharmacy and Anesthesia" appearing in the August 3 issue of the *Journal* are misleading. The writer of that editorial "wonders how the anesthetist knows that 1/200 gr. of scopolamine is going to contribute to the success of the anesthesia." He further states that the anesthetist should "limit himself to a moderate dose of atropine, together with a suitable dose of atropine or some substance having the pharmacologic effect of atropine." A little reading in preparation for the editorial would have disclosed that scopolamine is a valuable sedative and that it effectively counteracts the respiratory depressant action of morphine if given in proper dosage. A short perusal of text on pharmacology would have revealed that scopolamine does have many of the valuable pharmacologic effects of atropine.

The fact that Sodium Luminal was given is lightly glossed over by the writer of the editorial. Long-acting barbiturates are usually not indicated as pre-anesthetic drugs.

The writer of the editorial, if he were at all familiar with anesthetic practices, would have been more concerned with

the action of spinal anesthesia in producing respiratory paralysis in this case rather than with attacking so strongly the pre-anesthetic drugs.

The use of coramine and carbon dioxide in the treatment of the respiratory depression as described is open to criticism.

The fact that satisfactory tidal exchange was established and maintained is a credit to the anesthetist.

The statement is made that when nurse technicians are employed to administer the anesthesia, heavy premedication is avoided because the surgeon gives the orders. This may be the experience of the one who wrote the article, but it is by no means universal.

The editorial recommends that the surgeon, in order to protect his patient, consult with the anesthesiologist in detail concerning each step of medication given before, during and after operation. It is certainly to be hoped that the surgeon will consult with the anesthesiologist in detail about each patient about to undergo anesthesia and surgery. For the better and fuller protection of the patient, I suggest that the surgeon choose a thoroughly qualified anesthetist and depend on the anesthesiologist's more thorough knowledge of sedatives to safeguard the patient against accidents. There is no clinician more familiar with the pharmacologic action of narcotics and hypnotics than the anesthesiologist.

It is stated that in the present state of anesthesia, there is too much art and not enough science. With this statement I take strong issue. An increase in the art and a tempering of the science of anesthesia would elevate the present status of this practice.

MEYER SAKLAD, M.D.
Director of Anesthesia

Rhode Island Hospital
Providence 2, Rhode Island

The above letters are typical of many that have been received from anesthesiologists in criticism of the editorial "Polypharmacy and Anesthesia." The editorial presented an abbreviated case report, and from the events described therein, it was deduced that the premedication was chiefly responsible for the alarming symptoms. It was assumed that the slow shallow respirations subsequent to the period of apnea were caused by this medication. This interpretation is questioned by expert pharmacologic opinion, and it appears likelier that the apnea and the depressed respirations were the result of a spinal anesthesia that had progressed too high. For this, the *Journal* humbly apologizes.

Nevertheless, it should still be pointed out that there is a large body of medical opinion, found perhaps more among surgeons than among anesthetists, that simplification of premedication is a goal to be sought in future advances in anesthesia. Although the excellent human experimental work of Waters and his associates referred to in the letter from the group of Boston anesthetists has indicated that combinations of morphine and scopolamine and of Pentobarbital Sodium and scopolamine are useful and, in moderate doses, safe, there are no similar studies in which the triple combination of morphine, scopolamine and a barbiturate has been given. In fact, as indicated by Dr. Saklad's letter, some anesthetists do not approve a combination of a long-acting barbiturate and morphine in premedication.

The discussion evoked by the editorial can do nothing but good. If it can be followed up by additional experimental work and by careful observation and analysis of large numbers of cases, it may be possible to work out a universally acceptable simple form of premedication for the less intricate operative procedures in healthy patients. — EN.

BOOK REVIEWS

The Permeability of Natural Membranes. By Hugh Davson, D.Sc.; and James F. Danielli, D.Sc., A.I.C. With a foreword by E. Newton Harvey, Ph.D. 8°, cloth, 361 pp., with 73 illustrations and 72 tables. New York: The Macmillan Company, 1943. \$4.75.

The great usefulness of this book will be obvious to all students of biology. The authors present a general survey of the field of permeability, including materials essential for students of medicine, physiology, biochemistry, zoology and botany. It is made clear that permeability studies have passed beyond the preliminary exploratory stage, having

CASE 3. A white soldier was admitted to the hospital with a history and physical findings similar to Cases 1 and 2. The working diagnosis was atypical pneumonia of the right upper lobe. This was confirmed by roentgenogram. The patient had a low-grade fever for 8 days following admission. A roentgenogram taken on the 11th hospital day showed some clearing of the pneumonic process. Since the persistence of physical signs in the chest and the slow clearing of the chest lesion despite clinical improvement of the patient are not usual in atypical pneumonia, sputum examinations were begun. Tubercle bacilli were found. This was confirmed in later examinations of the sputum.

Summary

Atypical pneumonia may simulate pulmonary tuberculosis both clinically and roentgenographically, and the reverse is equally true.

Approximately 7 to 10 per cent of atypical pneumonias have upper-lobe involvement, which is the usual site for pulmonary tuberculosis.

Serial roentgenograms showing apical lesions failing to clear in twenty days following the onset of the disease should raise the suspicion of pulmonary tuberculosis.

Sputum studies for tubercle bacilli are indicated in all doubtful cases.

If lesions persist for twenty days from the onset of the illness, and routine sputum studies are negative, further studies should be done, that is, sputum and gastric concentrates and guinea-pig inoculation.

Because of the apparent increase in the incidence of atypical pneumonia, the need for an early differential diagnosis is imperative. — Reprinted from *Tuberculosis Abstracts* (November, 1944).

CORRESPONDENCE

"POLYPHARMACY AND ANESTHESIA"

To the Editor: In the August 3 issue of the *Journal* there appeared an editorial entitled "Polypharmacy and Anesthesia" which seems to call for some reply from those of us practising as specialists in anesthesiology. A case is cited in which preliminary to procaine-pontocaine spinal anesthesia for appendectomy in "a healthy, seventeen-year-old boy" premedication of "1/6 gr. of morphine, 1/200 gr. of scopolamine and 2 gr. of Sodium Luminal" was given "by injection." Information is lacking as to the intervals before induction of anesthesia at which these drugs were administered, as is any statement about the dosage of procaine and pontocaine or the spinal level attained by the subarachnoid block. Respiratory depression or failure supervened fifteen minutes after induction of anesthesia, and was ascribed by the writer of the editorial to the preliminary medication. Although it seems much more likely, on the basis of the account, that the respiratory difficulty was caused chiefly if not entirely by the ascent of the spinal drugs to a high level, and not by the medication, pharmacologic questions are raised that should be answered. "One wonders how the anesthetist knows that 1/200 gr. of scopolamine is going to contribute to the success of this procedure. Would not 1/4 gr. or even 1/2 gr. of morphine achieve approximately the same effect? One also wonders, but not so seriously, whether the Sodium Luminal was necessary?"

To answer these queries in order: The anesthesiologist knows from his clinical experience and from his knowledge of pharmacology that 1/200 gr. of scopolamine will probably contribute to the success of spinal anesthesia. One quarter or one third of a grain of morphine would not achieve approximately the same effect, because the pharmacologic effects of morphine differ fundamentally from those of scopolamine. It could be said that the Sodium Luminal (phenobarbital) is not absolutely necessary, but it contributes to the comfort and safety of the patient.

The combination and dosage of the three drugs mentioned, far from being "a practically fatal combination of sedatives," is commonly prescribed by anesthesiologists and is well within the limits of safety. Each is employed for a definite purpose. The barbiturate, in addition to its soporific effect, protects against possible toxic reaction to the local anesthetic drugs. Goodman and Gilman¹ state: "Soporific doses of the

barbiturates are only slightly depressant to the respiration; [while] morphine is a primary and continuous depressant of respiration by virtue of a direct action on the respiratory center. The effect is discernible with small doses insufficient to produce sleep or disturb consciousness. The action is a highly selective one, and the depression is directly proportional to the dose."

Sedation produced by the combination of the two drugs in moderate dosage results in less respiratory depression than would result from a large dose of morphine alone.

Scopolamine, although apparently considered by the writer of the editorial as a sedative, in reality belongs to the atropine group of drugs. We again quote Goodman and Gilman¹: "Scopolamine, like atropine, has a potent inhibitory action on secretions, but in addition, the alkaloid is also a depressant of the central nervous system and reduces excitement. Scopolamine is often viewed as a respiratory depressant, but this action on the medullary center has been exaggerated. Indeed strong evidence from clinical experiments of Waters and his associates² indicates that the depression of breathing by morphine can be completely counteracted by doses of scopolamine, so that otherwise poisonous amounts of morphine may be administered to man without lowering the normal respiratory exchange."

It appears unprofitable to discuss the opinions expressed in the latter part of the editorial. We hope that the opening paragraph better reflects the beliefs of the majority of members of the medical profession: "The scientific advances in anesthesia in the last decade have been truly spectacular, and largely because of them, surgeons have been able to operate successfully in many regions of the body previously inaccessible. Furthermore, the safety of other operative procedures has been increased by these new methods, provided they are expertly applied."

BOOK REVIEWS

The Permeability of Natural Membranes. By Hugh Davson, D.Sc., and James F. Danielli, D.Sc., A.I.C. With a foreword by E. Newton Harvey, Ph.D. 8°, cloth. 361 pp., with 73 illustrations and 72 tables. New York: The Macmillan Company, 1945. \$4.75.

The great usefulness of this book will be obvious to all students of biology. The authors present a general survey of the field of permeability, including materials essential for students of medicine, physiology, biochemistry, zoology and botany. It is made clear that permeability studies have passed beyond the preliminary exploratory stage, having

reached the stage at which quantitative analysis is of dominant importance. In the foreword, Professor E. Newton Harvey, of Princeton University, writes in part: "Just as chemistry could not have developed without test tubes to hold reacting substances, so organism could not have evolved without relatively impermeable membranes to surround the cell constituents. This barrier between the inside and the outside, the inner and external world of each living unit, has been and always must be considered one of the fundamental structures of a cell." Each of the twenty-one chapters is followed by a series of references, and an excellent index is provided. The last chapter deals with the theories of cell permeability.

Traumatic Injuries of Facial Bones: An atlas of treatment. By John B. Erich, D.D.S., M.D., and Louie T. Austin, D.D.S. In collaboration with the Bureau of Medicine and Surgery, United States Navy. 12°, cloth, 600 pp., with 333 illustrations. Philadelphia and London: W. B. Saunders Company, 1944. \$6.00.

In this book the authors attempt to present a manual for the treatment of injuries of the facial bones. General considerations are covered in eleven printed pages. As the subtitle suggests, the book is a pictorial of treatment. The illustrations are well done, and should appear clear to the student, but many seem exaggerated in showing the nature of the wounds.

The methods of immobilizing the facial bones are described in great detail, and the authors explain many elaborate and complicated appliances for use in cases in which it seems likely that simple procedures of proved value would accomplish the same results. The book, however, is a valuable contribution to the literature on injuries of the face.

Clinical Tropical Medicine. Edited by Z. Taylor Bercovitz, M.D., Ph.D. With a foreword by Wilbur A. Sawyer, M.D. 4°, cloth, 957 pp., with 121 illustrations. New York: Paul B. Hoeber, Incorporated, 1944. \$14.00.

This book contains chapters by twenty-seven authors who are well known for their work in the field of tropical medicine. The editor of the volume, Dr. Bercovitz, has also contributed chapters on many of the important tropical diseases, including amebic dysentery, malaria and certain of the helminthic diseases.

Dr. Charles F. Craig has written the chapters on spirochetes and spirilla, except pinta and yaws, which have been covered by Dr. Howard Fox. Dr. Henry Pinkerton has dealt with the diseases caused by rickettsias; Dr. Edward B. Vedder, with the nutritional diseases; and Dr. Morris Moore, with the diseases caused by yeasts and fungi. The other authors have contributed importantly but less extensively to the volume. Most of the numerous illustrations are excellent.

The book is valuable because of the authoritative contributions that it contains, but its highest levels of quality are not uniformly sustained. Here and there can be found statements that are ambiguous, misleading or incorrect. For example, under amebiasis, it is said that food and water should be boiled "for at least thirty minutes" to destroy cysts, whereas, since amebic cysts in water cannot survive a temperature of 50°C. for more than a few minutes, prolonged boiling is needless. In the chapter on malaria, a serious error occurs: it is stated there that the sporozoites "enter the blood stream and attach themselves to the red blood corpuscles." Although it is not known what happens to the sporozoite after it passes from the mosquito into the human body, it is quite possible that the parasite undergoes important changes during the interval of several days that elapse before it makes its appearance in the red cell. Finally, in the chapter on beriberi, a distinction is drawn between beriberi and "the peripheral neuritis caused by alcohol." There is no convincing evidence that peripheral neuritis in man has ever been caused by alcohol per se, most physicians now believing that it results from a dietary deficiency that is secondary to the alcoholism.

Even though the book contains passages that are open to serious criticism, it contains much that is excellent.

NOTICES

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a. m.

MEDICAL CONFERENCE PROGRAM

Friday, December 1 — Surgical Aspects of Intestinal Infections. Dr. Jost J. Michelsen.

Wednesday, December 6 — Practical Aspects of Shock Therapy. Dr. Arthur Berk.

Friday, December 8 — Alloxan Diabetes: Clinical and pathologic findings. Dr. C. Cabell Bailey and Orville Bailey.

Wednesday, December 13 — Some Effects of Injected chrome C in Animals and Man. Dr. Samuel Prosser.

Friday, December 15 — The Cushing Syndrome. Dr. Kenneth W. Thompson.

On Monday mornings clinics will be given by Dr. Prosser. On Tuesday and Thursday mornings Dr. Thannhauser will give medical clinics on hospital cases. The medical profession is cordially invited to attend.

MASSACHUSETTS PSYCHIATRIC SOCIETY

On Tuesday, December 5, the Massachusetts Psychiatric Society will tender a dinner to Brigadier J. R. Reese, F.R.C.P., consulting psychiatrist to the British Army medical director of the Tavistock Clinic, London. It served at 6:30 p. m. at the Kenmore Hotel, Boston. Brigadier Reese will speak on the subject, "The Shaping of Psychiatry by War," and his lecture will be of importance not only to psychiatrists and physicians but to everyone interested in the present trends in psychiatry and the associated particularly in relation to the war and the postwar period.

The tickets, \$2.90 each, must be purchased on or before December 2 from Dr. Earl K. Holt, Box A, Harding, Massachusetts.

HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society will be held in the amphitheater of the Peter Bent Brigham Hospital on Tuesday, December 12, at 8:15 p. m.

NEW ENGLAND OBSTETRICAL AND GYNECOLOGICAL SOCIETY

A clinic of the New England Obstetrical and Gynecological Society will be held at the Carney Hospital on December 9 at 9:00 a. m. in the operating room on the sixth floor. Louis E. Phaneuf, Roy J. Heffernan and Maurice O. Belson will perform gynecological operations.

At 10:30 a. m. a dry clinic will be held in the auditorium.

PROGRAM

The Repair of the Lacerated Perineum. Dr. Louis E. Phaneuf.

The Role of the Transverse Cervical Cesarean in the Management of Placenta Previa. Dr. Roy J. Heffernan.

The Management of the Third Stage of Labor. Maurice O. Belson.

Sternal Transfusions in Obstetrics and Gynecology. Meyer D. Schnall.

AMERICAN PUBLIC HEALTH ASSOCIATION

The third wartime conference and seventy-fourth annual meeting of the American Public Health Association will be held in Chicago during the week of September 17, 1945, with headquarters in the Hotel Stevens.

The Chicago program will cover subjects of interest to health officers, public-health nurses, laboratory workers, nutritionists, vital statisticians, engineers, child-health specialists, maternal-health specialists, health educators, public-health dentists, epidemiologists, industrial hygienists and others working in the broad field of health protection and promotion.

THE STUDY OF THE PATIENT FROM A PSYCHOSOMATIC STANDPOINT*

KENNETH J. TILLOTSON, M.D.†

BELMONT, MASSACHUSETTS

AMONG the most recent advances in medicine resulting directly from the present war are the employment of the sulfonamides and penicillin to combat infection and that of blood plasma to combat shock. Both depend on their prompt use after injury, and delay may result in loss of the therapeutic opportunity. A third and comparable medical contribution may be added — the early recognition of psychoneurotic or emotional symptoms and their prompt treatment and management. Failure to recognize the nature of these emotional manifestations may mean delay in promptly and effectively treating the patient. Psychoneurotic disorders manifest themselves in the following manner: pain, headaches, nervousness, indigestion, dizziness, weakness, backaches and a host of other somatic complaints. These physical signs of emotional maladjustment are termed "psychosomatic symptoms." First aid in the form of prompt psychiatric treatment has already become as valuable to the armed forces and to the people of civilian areas under bombardment as have the quick recognition of a physical injury and the knowledge of how and where to apply a tourniquet to control bleeding.

There is a close parallel between first aid for physical casualties and that for so-called "mental casualties," also known as emotional maladjustments or nervous conditions, or, perhaps more correctly, psychoneuroses or psychosomatic reactions. The immediate treatment of these complaints — often severe or hysterical in character, and at times even constituting excited or psychotic reactions — forms a valuable therapeutic contribution, since a large percentage of patients with these previously disabling disorders are now completely cured, and considerable numbers of men in the armed forces are even returned promptly to active combat duties.

This method of treatment is called "narcosynthesis," and consists of administering Pentothal Sodium intravenously until a certain stage of narcosis is reached. When in this state, the patient re-experiences the intense emotions that were originally associated with the traumatic battle experiences

and that have been perpetuated in various stages of repression up to the moment of treatment. He actually synthesizes the emotions and memories connected with the experience. Under the influence of the drug the physician uses psychotherapy to free the patient of the intense repressed emotions that cause the neurotic symptoms, and the latter emerges from the narcosis with relief from his abnormal reactions and with new emotional drives, and returns in a state of renewed strength to a world of reality, both past and present. In certain cases in which the narcosynthesis does not produce the desired result, electric shocks may be given. Both the foregoing procedures depend on marked physiologic changes produced either chemically or electrically, as well as psychotherapy, to reverse the psychologic state of the patient. These newer methods and procedures have already altered the nature of present-day psychiatric practice, and it is probable that further and equally revolutionary changes will follow with the increasing demand for psychiatric treatment resulting directly or indirectly from the present war.

Prior to World War I, neuropsychiatric disorders were treated most unsatisfactorily and by a comparatively small group of psychiatrists and neurologists, most of whom were attached to mental hospitals. Such complaints and symptoms could not be dealt with in the forthright manner in which most medical symptoms were approached, for popular sentiment — including the attitude of the medical profession — toward nervous and mental diseases was extremely unscientific and at best depicted little understanding. In World War I, however, under the spur of necessity, there was revealed not only the frequency with which neuropsychiatric complaints occur but the high percentage of psychoses and psychoneuroses existing in the civilian population. Attention was also drawn to the psychosomatic elements that affect a large number of persons who, to be sure, are suffering from medical or surgical conditions, but whose treatment and management are severely complicated by emotional or psychoneurotic factors. There was thus introduced an entirely new field of thought, and in this

†Instructor in psychiatry, Harvard Medical School; psychiatrist-in-charge, McLean Hospital.

way there began the development of present-day psychosomatic studies that are applicable not only to neuropsychiatric patients but to all patients.

Twenty years ago, when many of those now in practice were medical students, psychiatry and the study of nervous disorders presented problems that seemed not only mysterious but infinitely complex. From the available literature and from the meager instruction current in medical schools at that time, it was difficult to obtain a concise and unbiased presentation of the mechanisms that underlie abnormal behavior and emotional disorders.

The professional vernacular presumed an acquaintance with much, although it was not a part of ordinary experience, and in lieu of actual experience with neuropsychiatric disorders as then understood, a few stereotyped descriptions of the vintage of Janet, Charcot, Babinski and Kraepelin served to give an understanding of neurologic and psychiatric disorders, together with equally unsatisfactory descriptions of the end stages of manic-depressive psychoses and dementia praecox. The medical profession as a whole had not as yet discovered the importance of the dynamic and emotional factors in psychologic medicine, nor did it realize that the psychologic components — namely, the emotional factors and neuropsychiatric disorders as such — were frequently not considered or missed in diagnosis. This state of things resulted in much unnecessary chronic illness, to say nothing of an immense amount of needless surgery.

The psychogenic hypothesis was first outlined by Brodie as long ago as 1837. It stressed the importance of the unconscious to the development of personality and to subsequent emotional experience — a subject that was later presented and elaborated by Freud, Jung and others. Generally speaking, twenty years ago little was known about psychodynamics, psychopathology and psychobiology; all of which means that nothing was known, practically speaking, of the tremendous field of the unconscious and its relation to the causes of psychoneuroses, the importance of psychosomatic relations and the early emotional manifestations and symptoms of all disease or illness.

In World War I, psychiatry began to be recognized as having an important contribution to make. For the first time it was given, although reluctantly, a place of slight responsibility along with the other medical specialties. With the development of post-war psychiatric problems in returning veterans, neuropsychiatric disorders began to be placed on a responsible medical footing. It remained for a better understanding of psychosomatic medicine and its integration with the daily practice of general hospital medicine to demonstrate its value. From the application of physiologic principles, together with a psychologic understanding of the patient, successful treatment of psychoneurotic disorders became an accomplished fact, and the field of neuro-

psychiatry could be said to stand on a firm scientific basis and from a clinical standpoint to compare favorably with other specialties.

How does this relate to the problems of mental health in the present armed forces and the mental health of the civilian population under the stress of the present war? It is frequently asked what the psychologic effects of war are on civilians and military personnel, whether the war has developed any new types of nervous and mental disorders, and whether present-day neuropsychiatrists and the medical profession in this country are adequately equipped to handle such conditions. The final answer rests on the ability of the medical profession to practice psychosomatic medicine and to face intelligently the ever-increasing emotional factors and their influence on personality as well as on the patient's physiologic state.

The psychologic effect of war on civilians and soldiers and sailors may be disastrous in that predisposed tendencies may become activated and emotional symptoms, a neurosis, a psychoneurosis or even an actual psychosis may develop. That these disorders are no different from the prevailing disorders of the last war, psychiatrists seem to agree. The so-called "shell shock" of World War I might be anything from a neurosis to a psychosis of the most profound character. The exhaustion or fatigue syndromes of the present war and the psychosomatic complaints are again a mere repetition of psychoneurotic complaints, varying in manifestation, intensity and duration and also in response to treatment, depending largely on the constitutional factors in the given patient. That there are not enough psychiatrists at the present time to deal with the vast number of neuropsychiatric casualties in the armed forces is evidenced from all quarters. For instance, some time ago a bulletin from the War Department stated that any medical officer might be called on to treat neuropsychiatric casualties because of the shortage of psychiatrists. The burden of treating these casualties will fall on medical officers without specialized training. This fact may be more vividly portrayed by the following figures. An average of 8 to 20 per cent of the men examined for military service are rejected for psychiatric reasons, and 40 per cent of the discharges from the armed forces are made for psychiatric reasons. In contrast, about 2 per cent of the members of the medical profession are neuropsychiatrists. In addition, one third of the neuropsychiatrists in this country are now in the armed forces. The social implication of these figures is enormous, but their importance to the medical profession and to the general practitioner is even greater and more challenging. Every physician is aware of the fact that even in peacetime 40 to 60 per cent of the patients seeking medical help present essentially emotional problems or frank psychiatric disorders. A major result of the war experience is the compelling necessity to focus at-

attention on a large section of the population who need medical care and who previously may not have recognized this need. No doubt there will also be a considerable increase in the number of patients with disabling functional illnesses seeking help from every specialty of the medical profession.

The most frequent diagnosis of these disabilities by far is that of psychoneurosis — a term that connotes a great number of clinical entities. Unfortunately, ordinary neuropsychiatric disorders have been thought to occur only in those with personality defects or, generally speaking, in weaklings. This is not true. A fair proportion of neuropsychiatric patients give no history of previous difficulties. Under the extremes of fatigue and the stress of modern combat, the most stable person may reach his breaking point. Thus the presence of neuropsychiatric disorders in combat must be looked for in the normal persons as well as those predisposed to such abnormal states.

In soldiers, the factors that precipitate emotional disorders with resulting psychosomatic symptoms include separation from home, regimentation, lack of freedom, lack of privacy, lack of feminine companionship, a feeling of not being appreciated and a lack of confidence in leaders. In combat, there are extreme fatigue, danger and long exposure to death, malnutrition, exposure to heat and cold, disease, isolation, confusion, hunger and the fear of being a coward or of losing one's self-control, as well as the realization of the responsibility for the lives of others, insufficient understanding of war or lack of the conviction to fight.

A distinction may well be made between the treatment and the management of psychoneuroses. Treatment depends on the type of disorder and its duration, the ability of the physician and the degree of rapport that is developed between him and the patient. Obviously a great many patients are treated without being cured. Probably few psychoneurotic subjects are treated by competent physicians without being relieved. The result obviously depends not only on the method of treatment and the ability of the therapist, but on the type of patient and the nature of the psychoneurosis.

If the study of psychosomatic factors and the approach to the patient are correct, the only rational method of treatment consists in the revealing to him of the unconscious mental processes that are responsible for the symptoms or illness as a whole, by bringing into consciousness the repressed impulses that find vicarious satisfaction in symptoms. The patient must be given an insight into why he has symptoms and how they are produced and what they mean at the psychologic or psychobiologic level, and must be shown that nervousness and emotional tension result from conflicts and frustrations. In some cases this is relatively easy. In many others, however, it is extremely difficult, because

therein lies the crux of the problem. Many psychoneurotic patients are highly intelligent and see the surface problem together with its ramifications and implications, yet are utterly at a loss to resolve it.

A psychoneurosis is not a matter of logic, and no amount of intellectualization will cure a state that is emotionally so deeply conditioned. Adjustment is not always or even generally possible, not alone because many of the inner emotionally toned conflicts are difficult to discover and resolve, but because most of the social and environmental factors are beyond the control of the therapist and many beyond the ability of the patient to mold to his own needs. If, however, the basic personality patterns cannot be changed, the patient may get relief through appreciation and understanding of the true nature of the illness.

Take, for example, a patient recently under treatment who had a typical neurasthenic type of psychoneurosis. A physician told her that the weakness and low blood pressure were indicative of a pituitary syndrome. He gave her many hormones and endocrine substances and had her remain in bed for months, but finally accomplished a fairly satisfactory shock treatment by telling her one day, "Of course you might as well know you have a serious pituitary disorder, Simmonds's disease, and you will gradually become a completely bedridden invalid." She was naturally quite overwhelmed and finally asked for a consultation. She was sent to a Boston hospital where an internist decided that she did not have the serious pituitary disorder, and ordered her out of bed. He informed her, however, that she did have a nervous disorder and referred her to a psychiatrist. Soon afterward she consulted me. Her co-operation in a reasonably active program, even including housework, which she had been told she would never be able to do, was excellent. More obvious conflicts, such as an incompatible sex relation with her husband occasioned by fear of pregnancy due to a severe and near fatal post-partum hemorrhage following her last childbirth, along with many other emotional problems, have been worked out. The development of a proper and hygienic routine of life and reassurance and definite proof that she can live an active, useful life constitute an improved state, and furnish a good example of the management of a psychoneurotic patient of the neurasthenic type.

Many acute tension and anxiety states must be dealt with on a symptomatic basis while the deeper and more fundamental psychologic factors are being explored. This necessitates management. If employment is cut off, a program of occupational therapy or physiotherapy and exercise must be instituted, unless a period of rest and heavy sedation is indicated. Small doses of drugs or refraining from the use of drugs is the safest policy unless a period of sedation is for some reason believed de-

sirable for the patient's immediate needs. In many cases chemotherapy enhances the value of psychotherapy.

An important point in the management of psychoneuroses is that the patient with psychogenic pain, headaches, insomnia, vomiting, tremors or feelings of tension, and combinations of these, believes that the symptoms are as real as an organic disease. Indeed, most patients insist that they would rather have pneumonia or surgical conditions requiring operation than this so-called "nervousness."

A patient with anxiety hysteria or obsessional states has a real illness, and reassurance may be of little value. He fears insanity, death, cancer, syphilis or some lingering disease. I treated periodically for several years a neurotic patient with the obsession that he had syphilis. Hinton tests and reassurance by a formidable array of outstanding medical consultants only gave him possible loopholes as he played one against the other. After a detailed medical, social and somewhat psychoanalytical approach through periods of free association, and after thorough physical examinations, it was finally discovered that at the age of twelve or fourteen the patient caught his mother in a sexual act with a man whom he later heard had syphilis. The emotional shock of the affair and his strong dislike for the man, together with the fact that his father had divorced the mother several years later because of her infidelity, made him build up a long and varied train of extremely painful conflicts. These revealed themselves in a real neurosis when he married, and his own marital situation suddenly overwhelmed him when he recalled an experience he had had in college with a prostitute while under the influence of alcohol. His long developing doubts and emotional conflicts were first manifested in anxiety; he then became fearful that he had contracted syphilis. When the steps of this development had been shown to the patient, he became much better. In fact, he made a good recovery over a period of two or three years, with several interruptions of otherwise fairly constant therapy.

To be successful, then, treatment must be directed to the individual problems of the patient and should reckon with his special personality profile. Psychotherapy actually begins the moment the patient enters the office, and both a detailed psychologic study and a careful physical examination are directed to that end. The physical examination, in particular, not only is useful for the purpose of excluding organic disease but serves as an excellent therapeutic measure in that it convinces the patient that his complaints are being seriously considered.

Nonne¹ wrote, "The war has shown that persons with a previously sound nervous system can acquire a neurasthenia complex, and hysteria is no rarity in war, even in persons hitherto quite healthy." An illustration of this fact is furnished by the ex-

perience of an officer from an American cruiser who had recently returned from the Mediterranean theater. Recounting his experiences in connection with his own neurotic disorders, he told of an experience concerned with the picking up of a transport plane in the Sicilian campaign. When the paratroopers in the plane had been commanded to jump, all had done so except an eighteen-year-old soldier. The officer leveled his revolver at the boy, who said, "Go ahead and shoot—I can't jump." When the paratrooper came aboard the cruiser, he wept hysterically, just as he had been seized with extreme terror and fright, which resulted in a complete numbness and inability to jump, when ordered to bail out, although always before in training he had experienced no trouble. The effect of this situation on the ensign was closely identified with his own anxieties and fears. The ensign wept bitterly and denounced the officer. "That yellow . . . tongue-lashed and threatened the poor kid all the way back to Africa amidst the suffering and groans of a boatload of wounded men." The ensign, who was on active duty, had consulted me believing he should resign from his naval post and return to civilian life to take up the study of medicine, since doctors were so badly needed. He thought that he could return to the front after completing his medical education and really do some good.

The outstanding cause of psychoneuroses, apart from a predisposition under actual service conditions, is undoubtedly fear of death or disablement. The symptoms exist because the patient is afraid, and they persist so long as there is any conflict between a desire for self-preservation and a sense of duty. If he is removed from duty permanently or if he refuses point-blank to face danger again, even to the extent of facing the disciplinary action or consequences that may be in store for him, he loses his symptoms, sometimes in a few hours. Other factors that have been alleged, such as guilt over killing, are infinitely rarer.

The psychosomatic study of the patient should begin with the complaint problem or the presenting symptoms. The underlying personality profile and emotional factors lead to evaluation of the part played by these emotions and anxieties in the development of the bodily symptoms. Queer behavior or conduct disturbances are not alone caused by psychologic or emotional factors. A review of recent publications in the field of psychosomatic medicine reveals that there is practically no physical disease or illness that is not caused or complicated by psychologic factors. This has been repeatedly demonstrated in such ordinary medical conditions as peptic ulcer and anorexia nervosa. The latter has been described as a psychosomatic entity, and in fact practically every medical disease is precisely that.

The psychosomatic approach must therefore take into consideration that the patient is a human

being with worries, fears, hopes and despairs, with the psychologic means of unconsciously converting these emotions into physical symptoms or of otherwise modifying the body physiology. This is most strikingly demonstrated in affective disorders, that is, in depressive states, from reactive depressions to manic states and involutional melancholia. A recent review of the results of electric-shock treatment of the foregoing disorders at the McLean Hospital not only demonstrates outstanding therapeutic results as compared to a control group treated without the aid of electric shocks, but clearly demonstrates the reversibility of the emotional or psychologic symptoms, with simultaneous dramatic changes in the body physiology.² The precise nature of these changes is not exactly understood, but the psychosomatic relations have been clearly demonstrated.

It may be of interest to note a few of the results of electric-shock treatment in a series of 70 patients with depressive states, as compared with a control group of patients suffering from the same types of depression but treated without electric shock. Eighty per cent of the treated group showed remission, as against 50 per cent of the control group. The quality and permanence of recovery in the shock group was almost twice as high as in the

other group, and the hospitalization of the former group varied from one to two months — 90 per cent less than that in the control group.

* * *

Psychiatrists have utilized the psychosomatic study of patients to a far greater extent since the use of the various shock therapies were introduced about ten years ago. The concept of the study and treatment of the personality as a whole on an individual basis has been one of the most important contributions of psychiatry to general medicine. Since physicians are now being called on to treat and manage an increasing number of psychoneuroses, as well as emotional states manifested by psychosomatic symptoms in a variety of illnesses, these psychosomatic considerations should be more widely accepted, utilized and integrated into the daily practice and experience of the general practitioner.

PILONIDAL CYST

An Analysis of 132 Consecutive Cases

LIEUTENANT COLONEL H. H. HAMILTON, M.C., A.U.S., LIEUTENANT COLONEL B. S. CUSTER, M.C., A.U.S., AND CAPTAIN A. KELLNER, M.C., A.U.S.

THIS study of the problem of pilonidal cyst is based on a review of 132 consecutive cases discharged from a station hospital from July 1, 1942, to October 1, 1943 — a fifteen-month period. At the beginning of the study, a method of preoperative classification and grading of cases was worked out. A policy was set and maintained throughout not to release a patient to duty until healing was complete. Various types of operations have been used during the study of this series of cases. Conclusions were reached after analyzing the first 66 operated cases. The preoperative classification of cases adopted was as follows:

Grade 1. On examination, the patient presents a sinus or sinuses and a palpable tumor, but there is no history of inflammation, that is, no local pain, swelling or discharge. If the case has been properly graded, the report of the pathologist indicates only fibrosis and giant-cell reaction, with minimal round-cell infiltration.

Grade 2. The patient presents a history of discharge and recurrent local tenderness and swelling, but not within the eight weeks prior to examination. Pathologically, the lesion of this grade of case shows chronic inflammation, as evidenced by a plasma-cell and lymphocytic-cell reaction.

Grade 3. The patient presents a history of recurrent discharge or previous abscess formation requiring drainage, or both. At the time of admission examination reveals local induration and tenderness. Pathologically, the lesions in these cases show acute and chronic inflammation, as evidenced by infiltration with neutrophils, lymphocytes and plasma cells.

Grade 4. At the time of examination the patient presents acute suppuration and abscess formation. Pathologically, there is gross pus and necrotic tissue.

Grade 0 (included for completeness). These cases are frequently referred for attention and are subclinical in type. Examination reveals a sacrococcygeal dimple that is completely epithelialized and contains no tumor mass at the bottom of the dimple. The tip of the coccyx invariably curves posteriorly, a point of great assistance in differential diagnosis. (In reviewing this series of 132 cases a single case of Grade 0 was noted; this was improperly classified as Grade 1 and failed to disclose any cyst on microscopic section.)

In arriving at the proper preoperative grading, white-cell and differential counts were of no benefit. Determinations of the erythrocytic sedimentation rate were also of little value. In borderline cases exhibiting no other evidence of disease within the previous three weeks, the sedimentation rate was of some value in so far as a rate above 10 mm. per hour by the Wintrobe method or above 15 mm. per hour by the Westergren technic, without any complicating disease, indicated that a careful, close study of the specimen should be made before the type of closure was decided on. Studies of frozen sections were carried out in a few cases of this type, but cutting of the cyst is difficult and the procedure is impractical. In order of importance, the results of physical examination, the history and the laboratory findings are the three items used in determining a grade.

This series was preoperatively graded as follows: Grade 1, 45 cases; Grade 2, 24 cases; Grade 3, 45 cases; Grade 4, 9 cases; ungraded, 9 cases. Four of the 9 ungraded cases did not come to operation because of separation from the service for other defects or a history of cysts that had been previously operated on, with breakdowns.

TYPE OF OPERATION

In evaluating this problem, 128 cases were considered since, as stated above, 4 of the ungraded cases did not come to surgery. The 5 remaining ungraded cases were all treated by excision and packing.

Excision and primary closure. This was done in 43 Grade 1 cases, with 1 failure (2 per cent); in 20 Grade 2 cases, with 2 failures (10 per cent); in 19 Grade 3 cases, with 10 failures (53 per cent); and in none of the Grade 4 cases. Failure is defined as any primary closure that required reopening or that on follow-up examination showed tissue breakdown or evidence of recurrence. The procedure of Ferguson and Mecray¹ (Figs. 1 and 2) was followed, with only minor modifications. With the patient in the Kraske position, and under a low-spinal or local anesthetic, the cyst and overlying skin are excised, strict attention being given to hemostasis. No preliminary injection of dye is used, and sutures of No. 50 black cotton are used on all bleeding points and to close the subcutaneous space. Three or four vertical mattress sutures of No. 30 steel-alloy wire are used

to approximate the sacrococcygeal fascia and tied over dental cotton rolls. Sutures of No. 50 cotton are used to approximate the skin. Postoperatively the patient is encouraged to lie on his back for at least an hour, and if possible, measures are

FIGURE 1. Schematic Cross Section of Modified Ferguson Operation.

taken to prevent defecation for five days to a week. The sutures are removed on the tenth postoperative day; the patient becomes ambulatory on the twelfth day and is returned to duty on the eighteenth to twenty-first day. In the 82 cases treated by primary closure, including the failures, the average time from operation to return to duty was twenty-five days.

Excision and packing. In the first 66 cases reviewed in this series 24 (37 per cent) were managed

FIGURE 2. Appearance of Site at Completion of Modified Ferguson Operation.

in this manner, and the average time of hospitalization was sixty-two days. Of the remaining 62 cases, only 4 received this type of management and the average period of hospitalization was one hundred and two days. This procedure has been almost entirely supplanted by partial closure.

Partial closure. The technic used in these cases was that of MacFee² (Figs. 3, 4, 5 and 6). This type of management was used in 11 of the final group of 22 cases. Nine of these cysts were Grade 3. 1 was

and ferric chloride 1 per cent) is applied to the granulating walls with an applicator, left for two minutes and flushed out with saline solution. This is done once daily until a clean, healthy, granulating surface is presented. These patients were discharged to duty as healed on an average of twenty-seven days after operation. Small areas of recurrence are

FIGURE 3. MacFee² Type of Partial Closure.

Mattress sutures of No. 20 cotton have been placed through the skin edges and fascia and are ready for tying.

Grade 4, and 1 was Grade 1, being too large for complete closure. The average time from operation to return to duty in this group was forty-five days.

Incision and drainage. This procedure was limited to 7 cases of gross suppuration and abscess formation.

FIGURE 5. MacFee² Type of Partial Closure.

The sutures are tied over small pieces of rubber dam, bringing the skin edges to the fascia without tension. In the lower sketch, showing a cross section, note that the sutures are left long.

FIGURE 4. MacFee² Type of Partial Closure.

This represents a cross section of the partial closure.

Nearly all these lesions were quite simple in type. Incision and drainage is done at the outset, and careful use of cauterizing agents effects a cure in simple types of abscess. Care is taken to excise the fistulous tracts at the time of operation, and 3 to 5 gm. of sulfanilamide powder is inserted, followed by loose packing, which is left for a week. After this, Carnoy's solution (absolute alcohol 6 per cent, chloroform 3 per cent, glacial acetic acid 1 per cent

apt to appear in this type of case, but none has been observed in this group, some of which have been followed for more than a year.

COMMENT

Grade 1 and Grade 2 cases have been satisfactorily closed by a modified Ferguson technic. Sixty-three cases were managed in this manner with 3 known failures. After discharge to duty, all these

patients have been re-examined at monthly intervals as long as they have remained on this field, and the follow-up study has been efficient enough so that delayed failures and recurrences may be considered to be extremely rare.

FIGURE 6. MacFee² Type of Partial Closure.

The wound is frosted with sulfanilamide powder, and the ends of the sutures are tied over a roll of iodoform gauze. This is covered with a pyramidal dressing of gauze. The iodoform roll and sutures are left in place for about ten days.

Grade 3 cysts should not be closed primarily, since this study shows a 53 per cent failure in cases so treated. Some form of partial closure, such as the MacFee operation, is recommended, inasmuch as the period of hospitalization is shorter, the local condition of the scar is better and the possibility of success is greater with partial closure than with the excision and open-packing operation. Since

it has become the policy of our services to close primarily only Grade 1 and Grade 2 cysts and to close partially all Grade 3 cysts, the average time of hospitalization has continued to fall.

It is recommended that the frankly septic cases be prepared preoperatively by hot sitz baths and local packs. Preoperative sulfonamides may be used by mouth, sulfanilamide may be dusted in locally at operation, and sulfadiazine may be given by mouth postoperatively.

To become proficient in preoperative grading, the surgeon should check his clinical grading of cysts with the report of the pathologist on the sectioned specimen. In addition, a careful history and physical examination are essential for proper grading; of these, the latter is the more important.

In this series of 128 cases that were operated on, the average hospital stay for all grades from date of operation to complete healing and return to duty was thirty-five days.

On this service the greatest problem in the care of pilonidal cystectomy applies to the excised cyst that has been left open and that heals with resulting excess scar formation. This scar mass tends to break down following trauma and superficial infection, resulting in shallow ulcers that are surrounded by dense fibrous tissue and are slow to heal. The plan adopted in such cases is bed rest, warm antiseptic packs and rigid aseptic technic in handling the dressing until healing is complete. The patient is then educated in the hygienic care and protection of the area before he is sent back to duty.

SUMMARY

It has been the purpose of this analysis to call attention to a method of preoperative grading of pilonidal cysts that has been helpful in determining those cases in which primary closure can be accomplished with a reasonable degree of success. No attempt has been made to bring forward any new type of operation, and all cases were treated by methods that up to this time have been accepted as being surgically sound.

THE USE OF GAUZE INOCULATED WITH *PENICILLIUM NOTATUM* OR IMPREGNATED WITH CRUDE PENICILLIN IN THE TREATMENT OF SURFACE INFECTIONS*

R. S. MYERS, M.D.,† R. H. ALDRICH, M.D., R. W. HOWARD, M.D.,‡ AND R. A. WALSH, B.S.§

BOSTON

RECENT reports indicate that topically applied penicillin solutions and creams are effective in controlling surface infections.¹ There have also been articles suggesting that gauze dressings inoculated with *Penicillium notatum* or impregnated with the crude penicillin have a similar effect. Robinson and Wallace² have described a method by which they believe that mold-inoculated dressings can be readily prepared by the physician. They noted subsidence of infection and relief from pain in patients with staphylococcal infections treated by this type of dressing. Hobson and Galloway³ report 10 cases (burns, lacerations, ulcers and infected sloughing wounds) in which gauze dressings moistened with the crude penicillin produced by *P. notatum* cultures were used. They prevented infection in 3 cases and helped to subdue and control it in 7. Fisher⁴ obtained encouraging results from using crude penicillin locally, but noted that it had distinct limitations. He believes that to be effective the dressings should be applied every two or three hours, that crude penicillin, like purified penicillin, is ineffective against certain organisms, and that it is less effective against long-standing infections than against those of brief duration. He noted no toxic effects when the crude penicillin was used either locally or parenterally.

The present clinical study was undertaken to evaluate the use of *P. notatum*-inoculated gauze dressings made according to the method described by Robinson and Wallace. Some of the cases were subsequently treated with dressings impregnated with crude penicillin. Bacteriologic studies were made to determine the bacteriostatic and bactericidal effects of each lot of mold or liquor.

Preparation of Gauze and of Crude Penicillin

Pieces of 28-by-24-mesh absorbent gauze were folded to form eight thicknesses, cut circularly, placed in clean Petri dishes and sterilized in a hot-air oven for one hour at a temperature of 400°F. Five hundred cubic centimeters of distilled water was next placed in an Erlenmeyer flask, to which

was added 6 gm. of dehydrated yeast and 12 cc. of glycerin. Finally, a separate mixture of 12 gm. of lactose, 12 gm. of cornstarch and 30

FIGURE 1. The *Penicillium notatum* Growing in an Erlenmeyer Flask.

The penicillin is secreted on the underside of the mold.

cc. of cold distilled water was added. The contents of the flask was stirred well and boiled for twenty minutes over a low flame. The Petri dishes and culture medium were cooled, and about 60 cc. of the medium was poured into each dish. A bit of the stock culture of *P. notatum* was then transferred to the plate with a flamed platinum loop. The dishes were placed in an incubator at a temperature of 23°C. The penicillin secreted during the growth process was deposited on the under-

surface of the gauze. Its concentration reached a maximum in twelve days and then rapidly retrogressed.

The medium used for the production of crude penicillin was a combination of 96 per cent nutrient broth and 4 per cent corn-steep liquor.* This was placed in flasks, which were sterilized by autoclaving, inoculated with *P. notatum* and incubated for about seven days at 23°C. The liquor, which was partially purified by filtration through a

cultures were made. Contaminated plates and flasks were discarded.

Method of Applying Dressings

Before the dressings were applied the lesions were prepared by cleansing with an aqueous cationic detergent or with hydrogen peroxide. Gauze pads inoculated with mold or impregnated with crude penicillin liquor were then applied and held in place by adhesive tape or bandage. Several cases

FIGURE 2. Gauze Inoculated with *Penicillium Notatum* in a Petri Dish.

Seitz filter, yielded a high titer of penicillin when assayed by the Oxford method.

The plates containing the impregnated gauze maintained their potency for about two weeks when kept at a temperature of 5°C. or lower, and the crude penicillin liquor could be kept for about four weeks at a temperature of 5°C. without any appreciable loss in titer.

All cultures were examined microscopically for bacterial contamination, and when necessary, sub-

of uterine cervicitis were also treated. In these, a pad of the mold-inoculated gauze or of gauze impregnated with crude penicillin was applied directly to the cervix. The dressing was held in place by a vaginal tampon for a period of thirty-six hours. Except for those on the uterine cervix, the dressings were renewed at intervals varying from one to four days. All the patients were ambulatory, thus making it difficult to change the dressings more frequently.

Types of Lesions Treated

Thirty-three patients with ulcers of the lower leg or ankle of one week to twenty years' duration were

*Corn-steep liquor is a by-product in the corn-refining industry and is obtainable from the Corn Products Sales Company, New York, New York.

treated for periods varying from two weeks to three and a half months. There were also 5 patients with chronic uterine cervicitis, 2 with postoperative lacerated-sinus wounds, 2 with breast wounds following radical mastectomy, in which there was necrosis of the skin and subsequent secondary infection, 2 with draining carbuncles, 1 with a small burn of the neck and secondary infection, 1 with a sloughing perineal wound and 1 with ulcerative stomatitis and secondary infection.

About half the cases were studied bacteriologically. Cultures were made before starting penicillin therapy and repeated during treatment. Most of them showed two or more types of organisms. Twenty-five cases exhibited *Staphylococcus aureus*.

Comment

The use of gauze inoculated with *P. notatum* or impregnated with crude penicillin was studied in 47 cases of surface infection. In view of the shortage of purified penicillin available for the treatment of surface infections, it was considered worth while to see whether such dressings could be conveniently prepared by the practicing physician. In our experience, homemade penicillin is much more difficult to prepare than is generally appreciated. Civilian physicians are advised to await a more plentiful supply of purified penicillin for the topical treatment of surface infections. Penicillin is too fickle a substance to be prepared by any except experienced hands. The parent mold is difficult to control, and

11, *Staph. albus*, 5, beta-hemolytic streptococci, and 4, *Escherichia coli*. A few lesions showed *Proteus vulgaris*, *Bacillus subtilis* and diphtheroid bacilli. After treatment most of the affected surfaces continued to show the same organisms, but in fewer numbers.

In the majority of the cases previous treatment had been employed. Sulfonamide ointments, cationic germicidal solutions, chlorinated solutions and boric-acid ointment were among the substances used without noticeable beneficial effect.

Results

The results of treatment with *P. notatum*-inoculated gauze and crude-penicillin dressings are shown in Table 1.

a painstaking bacteriologic technic is required to avoid contamination.

Most of the cases treated in this series were mixed infections, showing more than one type of organism on culturing. The cases that had a pure culture of penicillin-sensitive organisms responded by healing. The cases that failed to heal continued to show the presence of the original infecting organisms, especially *E. coli*, *P. vulgaris* and *Staph. aureus* (a nonsusceptible strain).

Chronic or mixed infections did not respond so well as did acute infections. In the group of 33 patients with chronic ulcers of the lower extremities, many factors other than infection prevented healing. In this group, a different form of therapy intensively followed would probably have given equally good results.

The 13 cases listed as improved, although not entirely freed from the infecting bacteria, were noticeably better in that the wounds looked less angry, were drier and did not have the offensive odor that was usually present before treatment.

No local or systemic toxic effects were noted in

Chronic or mixed infections did not respond so well as did acute infections or those infected with but one strain of a penicillin-sensitive organism

Because of the difficulties associated with preparing crude penicillin and mold-inoculated gauze, physicians are advised to employ only purified

any of the patients treated by these methods. There was no evidence of sensitivity, and the patients reported the dressings to be comfortable.

penicillin for the treatment of cases of surface infection

SUMMARY

Forty-seven cases of surface infection were treated with *Penicillium notatum*-inoculated gauze dressings and crude penicillin. Twenty-five cases healed and 13 improved during treatment.

MEDICAL PROGRESS

ENDOCRINE ASPECTS OF CANCER*

IRA T. NATHANSON, M.D †

BOSTON

THE earliest investigations concerning the relation of hormones to the genesis of tumors relied on indirect evidence. It was not until the isolation and identification of the action of certain of the sex hormones that the problem could be pursued on a more direct basis. Moreover, several of the synthetic carcinogenic hydrocarbons were found to have a basic chemical structure similar to cholesterol and to the hormones of the gonads and adrenal glands. Thus, experimental and clinical studies were further stimulated by the idea that atypical metabolism of the hormones might lead to oncogenesis. As a result of these observations, much information has been accumulated on the role of hormones in carcinogenesis. A symposium on the endocrinology of neoplastic disease was published in the July and August, 1944, issues of *Surgery*. The writer has drawn on these excellent articles,

as well as on other leading reviews, as one source of material. The present report summarizes and evaluates, so far as possible, some of the more significant experimental and clinical aspects of the relation of the hormones to carcinogenesis.

EXPERIMENTAL OBSERVATIONS

It is considered important in this review to cite the pertinent animal experiments so that they may be correlated, if possible, with clinical observations. Animals lend themselves readily to studies on cancer, since many develop spontaneous tumors that are similar to those in the human being. Therefore, the subject is reviewed from this standpoint, but it is necessary to stress that caution in interpretation is essential.

Tumors of Breast

Cancer of breast. The early observations of Tyzzer,¹ Slye² and others established the role of heredity in the development of tumors in mice. Later studies revealed that other factors were also involved.³ Thus, it was demonstrated that ovar-

tomy caused a marked reduction in the incidence of spontaneous mammary cancer⁴ and delayed the appearance of those tumors which arose in female mice having a high susceptibility to the disease.^{5,6} The reduction in rate varied directly with the age of the mouse at castration, except in newborn mice; for example, the younger the age at ovariectomy, the lower the incidence of tumor. The incidence of breast tumors in mice spayed immediately after birth was higher than in mice castrated at maturity.⁷ It has been postulated that after castration in newborn mice the adrenal glands, which secrete steroid hormones, substitute for the ovaries, since mammary and uterine stimulation were noted and adrenocortical hyperplasia developed later in life.⁸ Mammary cancer was produced in the male mice of a highly susceptible strain by the transplantation of the ovaries of their sisters,⁹ and it was further noted that the incidence of tumors in the female could be reduced by the implantation of testes.¹⁰ Ordinarily, male mice do not develop cancer of the breast. It was also observed that the breast cancer rate was lower in virgin than in breeding females.¹⁰ Forced breeding increased the incidence of breast tumors over that of normally breeding mice.¹¹ Claims that abnormalities in the sexual cycle are a factor have not been proved.¹² All these experiments suggested the importance of the ovary in the production of such lesions.

After the identification of the estrogens, attempts to produce breast cancer with these hormones were not successful until 1932. Lacassagne¹³ was the first to report the appearance of breast cancer after the injection of estrogens in male mice of a strain in which the incidence was high in the female. It was not possible to initiate the disease in males belonging to a strain in which the incidence of mammary tumor was extremely low.¹⁴ Many others have since confirmed and extended these studies.^{15,16,17} The administration of estrogens of different chemical structure¹⁴ and synthetic estrogenic preparations, such as diethylstilbestrol^{18,19} and triphenylethylene,²⁰ which are not directly related to the natural compounds or hydrocarbon carcinogenic agents, produced the same effect. Thus, it appears that any compound with the same physiologic effect can elicit the disease and that it is not dependent on a specific chemical structure of the hormone.²¹

Recently, Bittner^{22,23} discovered that a third factor, present in the milk of high-tumor-strain mothers, was essential to the development of mammary cancer. The suckling of newborn females of a low tumor strain on high-tumor-strain mothers significantly increased the incidence of cancer of the breast. A reduction in rate was noted if the situation was reversed. Twombly²⁴ utilized this foster nursing technic and found that it was possible to initiate mammary cancer in male mice of a low tumor strain when they were injected with

estrogens. It has been maintained that the extent of response of breast tissue of nonsusceptible animals to estrogens is limited regardless of the duration or the amount of hormone administered. Factors that ordinarily govern cell growth may prevent further progression of cells to a malignant state. Defects in the governing mechanism may allow for neoplastic change, provided the cells are susceptible. Geschickter's^{25,26} reports are at variance with this point of view. Rats ordinarily have a low incidence of mammary cancer. He noted a high incidence of mammary cancer in the rat induced by the prolonged administration of estrogens to apparently nonsusceptible animals. Metastases were also observed. Noble, McEuen and Collip,²⁷ using essentially the same method in a different strain of rats, noted tumors that were extremely hyperplastic. The tumors were not considered to be malignant, even though they resembled the lesions described by Geschickter. Moreover, regressions occurred after removal of the hormonal stimulus.²⁸ If it is confirmed that mammary cancer can be produced in a species with a nontumor genetic constitution, the role of estrogens as etiologic factors may assume greater significance.

The incidence of breast cancer in mice can be increased by the transplantation of the anterior lobe of the hypophysis under conditions that make possible the long survival of the transplant. Loeb and Kirtz^{16,29} found that transplantation of the glands from several brothers to a sister in a high tumor strain appreciably raised the incidence of mammary cancer. This did not occur in the strains in which the susceptibility to tumor was slight. Moreover, cancer could not be induced in the female of the high tumor strain in the absence of the ovaries. Therefore, the increased incidence of cancer was presumably brought about by an increased estrogen production resulting from pituitary stimulation of the ovaries in the intact animal.

Attempts have been made to influence the incidence and course of spontaneous mammary cancer in mice by the administration of gonadotropins. Chorionic gonadotropins had no effect, regardless of the age of the animals at the onset of the experiment, even though there was pronounced enlargement of the ovaries.³⁰ Equine gonadotropin (pregnant mare's serum) and pituitary gonadotropin retarded the onset and decreased the incidence of the cancer in the virgin mouse when treatment was commenced at approximately one month of life.³¹ Administration of the same hormones commencing when the mice were seven months old (the early cancer age) increased ovarian size but did not appreciably alter the onset and course of the tumors.³² The decrease in incidence produced by these hormones in the young immature animal may be related to the formation of antihormones, which in time would result in ovarian and mammary atrophy.

Thyrotropic extracts have been reported to have an inhibitory effect on the development of mammary cancer,³³ but this has not been confirmed.³⁴ Hypophysectomy at an early age theoretically reduces the incidence of spontaneous mammary tumors in mice if the animal can be maintained. Gardner,³⁵ however, found that if mice bearing spontaneous tumors were hypophysectomized in the last half of pregnancy or post partum the tumors grew progressively and new tumors frequently appeared.

Nathanson and Andervont³⁶ and others^{12,37,38} have found that testosterone will significantly lower the incidence of spontaneous mammary cancer in a highly susceptible strain. This is presumably brought about by an antagonism to the estrogens or the inhibition of the pituitary gland, which results in ovarian atrophy, or both. Desoxycorticosterone acetate³⁹ and progesterone⁴⁰ have no influence on the incidence or course of spontaneous breast cancer. None of the hormones tested thus far^{12,36} or hypophysectomy³⁵ has any effect on the course of a tumor once it has developed. No significant difference in the excretion levels of estrogens and 17-ketosteroids has been found between strains with high and low rates of spontaneous mammary tumor.⁴¹

It is now agreed by most observers that at least three factors are necessary for the genesis of breast cancer in the mouse. These are a heredity factor, the presence of the ovaries or their secretion and the milk influence. All three must be present or cancer does not develop in the experimental animal.²³

Fibroadenomas of breast. Spontaneous mammary cancer in the rat is infrequent, but fibroadenoma is a relatively frequent disease. One strain, with a relatively high incidence of the tumors, exhibited prolongation of the estrous cycle and a deficiency in ovulation.⁴² The initiation of fibroadenomas was attributed to the unopposed action of the estrogens resulting from abnormalities in the sexual cycle. It has been reported that estrogens given over a long period of time produce a high percentage of true fibroadenomas in a strain of rats that ordinarily have a low spontaneous incidence.²⁶ Others have been unable to confirm this, but the techniques were not identical.⁴³ Studies relative to hormonal influences on the histologic appearance of the tumors are more conclusive. Estrogens stimulate the epithelial elements of early spontaneous, autotransplanted or homotransplanted fibroadenomas and produce adenomas and cystadenomas.⁴⁴ Androgens^{44,45} and progesterone,⁴⁶ on the other hand, inhibit the epithelial component and produce fibrosis. Prolonged administration of estrogens revealed foci of abnormal proliferation of the epithelium in the tumors, which in some cases resembled cancer.⁴⁷ Thus it can be seen that in contrast to true cancer, the course and histologic appearance of benign tumors can be altered by hormones.

Tumors of Uterus

Cancer of cervix. Overholser and Allen⁴⁸ in 1931 reported the production of a lesion in the cervix in the monkey following estrogen injection that they believed to be carcinoma. Later studies by them⁴⁹ and by others^{50,51} revealed that the lesion was actually squamous metaplasia. This type of lesion was shown to regress after such a stimulus was removed or when progestin was given with the estrogen.⁵ Nevertheless, in 1936 several investigators described the appearance of a carcinoma-like lesion in the cervix of the mouse after estrogen was administered.^{52,53} This was of great interest, since cervical cancer does not develop spontaneously in the mouse. Subsequently, the production of cancer of the cervix and vagina after estrogen administration in the mouse has intensively been studied.^{12,54-56} The lesions are of the squamous-cell type since the mouse has no mucous glands in the cervix.⁵⁷ Early experiments were done in mice that were susceptible to mammary cancer. These studies were complicated by the fact that breast lesions developed before cervical lesions. It was therefore essential to remove the breast cancers as they arose.⁵⁴ This pitfall was overcome when it was noted that estrogens could induce cancer in strains of mice that were resistant to mammary cancer.⁵⁷ Hence, in contrast to the strain specificity necessary in the development of cancer of the breast in the mouse, the neoplastic response of the cervix to estrogens was not particularly governed by this characteristic. Consequently, there was scant evidence to prove a hereditary influence. Simultaneous administration of androgens or of progestin to any strain of mice did not alter the incidence of cervical cancer.⁵⁷ It was also established that the milk influence was not necessary.⁵⁷ Since there might be considerable doubt regarding the histologic diagnosis of cancer, several investigators proved the autonomy of the lesion by successful transplantation into other animals of the same strain.⁵⁴

Cancer and hyperplasia of endometrium. Estrogens can produce typical hyperplasia of the endometrium in animals.⁵⁸ If treatment is commenced before puberty or is prolonged, squamous metaplasia of the epithelium of the endometrium may occur.⁵⁹ Estrogens frequently produce pyometra,^{15,60} and some believe that this is the cause of the hyperplasia.⁶¹ Cystic hyperplasia in rabbits,⁶² guinea pigs⁶³ and monkeys⁶⁴ similar to that seen in the human female has been observed following prolonged treatment with estrogens. Hypophysectomy increases the susceptibility to the production of endometrial metaplasia not only with estrogens but also with androgens and progestin.⁶⁵ Hyperplasia and atypical proliferation of the endometrium follows partial ovariectomy in the guinea pig.⁶⁶ Irradiation of the ovaries in the guinea pig⁶⁷ and implantation of testicular tissue in mice⁶⁸ also result in endometrial

and a progressive erosion of the corpus is suggested by the fact that hyperplasticity induced in the experimental animals by the administration of the oestrogens are not re-inhibited by oestrogens if given simultaneously.¹¹ There is erosion of the uterus and the cervical and production of cancer of the endometrium. This is of interest because the rat is usually susceptible to oestrogen in cancer.¹² Gould¹³ found that spontaneous activity in the rabbit's endometrium. The rabbit was said to be oestrogenic, arose in the uterus of relatively old animals and gland atrophy and metastasis. Changes in those caused by oestrogens were found in rats. These oestrogens occurred frequently in the endometrium of pregnancy, which is produced after damage and hence an oestrogenic effect.

Uterus. Numerous attempts to induce cancer of the uterus in species such as mice, rabbits have been without success. The rat is especially susceptible so that these may be induced simply by the injection of oestrogens.¹⁴ The tumors arise usually between the myometrium but sometimes between the uterus thus covering hemithyphal. It appears throughout the abdominal cavity.¹⁵ Many are subperitoneal, and a large number of malignant epithelial carcinomas are found in the peritoneal fluid or ascitic endometrium.¹⁶ They occur in relation to the mechanism of the end system. Some of the lesions are considered malignant since they involve adjacent structures like the pancreas, liver and abdominal cavity and are not uncommonly because regression when treatment is discontinued.¹⁷ Another to another animal is unsuccessful. It has been injected with oestrogens.¹⁸ If one or two oestrogens¹⁹ or oestrogenic hormones²⁰ is injected simultaneously with the oestrogenic hormone. The induction system in the uterus pig is therefore a good one for studies susceptibility to tumor formation.

Primary Ovary

Primary tumors of the hypophysis seldom occur in rats. In 1950 three groups of rats²¹ reported hyperplasia of the pituitary and the formation of chromophobe adenomas and also of both sexes after treatment with oestrogens. These adenomas may be found in other animals of the same strain, but when the dose is treated with oestrogen.²² The adenomas of the intermediate lobe of the pituitary have also been observed after oestrogen.²³ These tumors change to car-

cinoma in all species of the same species, which demonstrates again the importance of a specific susceptibility to tumor formation. A more detailed review of the subject was recently written by Selby.²⁴

Primary of Ovary

Tumors of the ovary of the rat have appeared after the injection of the oestrogens.²⁵ In most cases the tumors arise in the ovary when spermatogenesis begins, but tumors have likewise been produced in the ovary when extracts of the anterior pituitary gland of sheep were injected in combination with oestrogen.²⁶ It has been suggested that the tumors arise from the primary germ cells as a result of stimulation of the gonocytes by gonadotropic hormones.²⁷ Seminomas have appeared after gonadotropin²⁸ in which case as the gland regressed, the spermatogenesis went on to tumor formation instead of undergoing normal differentiation. This effect was ascribed to excessive secretion of the gonadotropic hormones as a result of the partial castration, a state that may also arise after oestrogen produced by the oestrogenic injections. Although the evidence is not conclusive for a hormonal origin, there appears to be a common denominator. All three methods of tumor production, apparently, are related to increased stimulation of the gonads by the gonadotropins.

The production of interstitial cell tumors of the ovary in certain strains of mice by the injection of oestrogens²⁹⁻³¹ suggests a more definite hormonal relation. Simultaneous injection of testosterone or a certain dose level does not prevent the appearance of tumors but the rate of change is retarded.³² In the sequence of events leading up to the development of these tumors progressive phases of atypical cells appear with atrophy of the tubules. This is manifested by the formation of three generations of Leydig cells. Tumors may arise from any one generation or from a combination of two or of all three generations of cells.³³ These tumors appear malignant and metastasize widely, particularly to the lymph nodes.³⁴ Transplantation to other animals is successful when the host is treated with oestrogen.³⁵ Long-protracted injections of equine gonadotropins elicited changes in the ovary of certain mice that resembled those seen in the early stages of the tumors developed by oestrogens.³⁶ Thus as in the case of the first tumors, the gonadotropic hormones may be responsible for the changes. Many of the tumors appear to function since the seminal vesicles and prostate of the animals exhibited an androgen effect.³⁷ Tumors of this type produced by any form of oestrogen appear to be species limited as well as strain limited. Like cancer of the mammary gland and cervix in the mouse, the tumors arise only after prolonged treatment and after the tissue fails to respond in the usual fashion, or has regressed.³⁸

Thyrotropic extracts have been reported to have an inhibitory effect on the development of mammary cancer,³³ but this has not been confirmed.³⁴ Hypophysectomy at an early age theoretically reduces the incidence of spontaneous mammary tumors in mice if the animal can be maintained. Gardner,³⁵ however, found that if mice bearing spontaneous tumors were hypophysectomized in the last half of pregnancy or post partum the tumors grew progressively and new tumors frequently appeared.

Nathanson and Andervont³⁶ and others^{12,37,38} have found that testosterone will significantly lower the incidence of spontaneous mammary cancer in a highly susceptible strain. This is presumably brought about by an antagonism to the estrogens or the inhibition of the pituitary gland, which results in ovarian atrophy, or both. Desoxycorticosterone acetate³⁹ and progesterone⁴⁰ have no influence on the incidence or course of spontaneous breast cancer. None of the hormones tested thus far^{12,36} or hypophysectomy³⁵ has any effect on the course of a tumor once it has developed. No significant difference in the excretion levels of estrogens and 17-ketosteroids has been found between strains with high and low rates of spontaneous mammary tumor.⁴¹

It is now agreed by most observers that at least three factors are necessary for the genesis of breast cancer in the mouse. These are a heredity factor, the presence of the ovaries or their secretion and the milk influence. All three must be present or cancer does not develop in the experimental animal.²³

Fibroadenomas of breast. Spontaneous mammary cancer in the rat is infrequent, but fibroadenoma is a relatively frequent disease. One strain, with a relatively high incidence of the tumors, exhibited prolongation of the estrous cycle and a deficiency in ovulation.⁴² The initiation of fibroadenomas was attributed to the unopposed action of the estrogens resulting from abnormalities in the sexual cycle. It has been reported that estrogens given over a long period of time produce a high percentage of true fibroadenomas in a strain of rats that ordinarily have a low spontaneous incidence.²⁶ Others have been unable to confirm this, but the technics were not identical.⁴³ Studies relative to hormonal influences on the histologic appearance of the tumors are more conclusive. Estrogens stimulate the epithelial elements of early spontaneous, autotransplanted or homotransplanted fibroadenomas and produce adenomas and cystadenomas.⁴⁴ Androgens^{44,45} and progesterone,⁴⁶ on the other hand, inhibit the epithelial component and produce fibrosis. Prolonged administration of estrogens revealed foci of abnormal proliferation of the epithelium in the tumors, which in some cases resembled cancer.⁴⁷ Thus it can be seen that in contrast to true cancer, the course and histologic appearance of benign tumors can be altered by hormones.

Tumors of Uterus

Cancer of cervix. Overholser and Allen⁴⁸ in 1933 reported the production of a lesion in the cervix of the monkey following estrogen injection that they believed to be carcinoma. Later studies by them⁴⁹ and by others^{50,51} revealed that the lesion was actually squamous metaplasia. This type of lesion was shown to regress after such a stimulus was removed or when progestin was given with the estrogen. Nevertheless, in 1936 several investigators described the appearance of a carcinoma-like lesion in the cervix of the mouse after estrogen was administered.^{52,53} This was of great interest, since cervical cancer does not develop spontaneously in the mouse. Subsequently, the production of cancer of the cervix and vagina after estrogen administration in the mouse has intensively been studied.^{12,54-56} The lesions are of the squamous-cell type since the mouse has no mucous glands in the cervix.⁵⁷ Early experiments were done in mice that were susceptible to mammary cancer. These studies were complicated by the fact that breast lesions developed before cervical lesions. It was therefore essential to remove the breast cancers as they arose.⁵⁴ This pitfall was overcome when it was noted that estrogens could induce cancer in strains of mice that were resistant to mammary cancer.⁵⁷ Hence, in contrast to the strain specificity necessary in the development of cancer of the breast in the mouse, the neoplastic response of the cervix to estrogens was not particularly governed by this characteristic. Consequently, there was scant evidence to prove a hereditary influence. Simultaneous administration of androgens or of progestin to any strain of mice did not alter the incidence of cervical cancer.⁵⁷ It was also established that the milk influence was not necessary.⁵⁷ Since there might be considerable doubt regarding the histologic diagnosis of cancer, several investigators proved the autonomy of the lesion by successful transplantation into other animals of the same strain.⁵⁴

Cancer and hyperplasia of endometrium. Estrogens can produce typical hyperplasia of the endometrium in animals.⁵⁸ If treatment is commenced before puberty or is prolonged, squamous metaplasia of the epithelium of the endometrium may occur.⁵⁹ Estrogens frequently produce pyometra,^{15,60} and some believe that this is the cause of the hyperplasia.⁶¹ Cystic hyperplasia in rabbits,⁶² guinea pigs⁶³ and monkeys⁶⁴ similar to that seen in the human female has been observed following prolonged treatment with estrogens. Hypophysectomy increases the susceptibility to the production of endometrial metaplasia not only with estrogens but also with androgens and progestin.⁶⁵ Hyperplasia and atypical proliferation of the endometrium follows partial ovariectomy in the guinea pig.⁶⁶ Irradiation of the ovaries in the guinea pig⁶⁷ and implantation of testicular tissue in mice⁶⁸ also result in endometrial

erplasia. A protective action of the corpus uterini is suggested by the fact that hyperplasia is easily induced in the experimental animal by injection of estrogens if the ovaries are not removed⁶⁹ or if progesterone is given simultaneously.⁷⁰ In contrast to cancer of the breast and the cervix, experimental production of cancer of the endometrium is rare. This is of interest because the endometrium is usually susceptible to estrogen stimulation. Greene⁷¹ found that spontaneous tumors develop in the rabbit's endometrium. The tumors, which were said to be adenomas, arose in the glandular mucosa of relatively old animals and spread by local extension and metastasis. Changes similar to those caused by estrogens were found in other organs. These adenomas occurred frequently in animals that had toxemia of pregnancy, which may have produced liver damage and hence an inability to inactivate the estrogens.

Uterine Myomas. Numerous attempts to induce myomas of the uterus in species such as mice, rats, and rabbits have been without success. The guinea pig is singularly susceptible so that these tumors may be induced simply by the injection of estrogenic hormones.⁷²⁻⁷⁴ The tumors arise usually in the subserosa and the myometrium but sometimes involve the mucosa, thus causing hemorrhage. They may appear throughout the abdominal cavity in both sexes.^{73,75} Many are subperitoneal, and although the site of origin is not definitely established, the earliest lesions are found in the peritoneal omentum⁷⁶ or celomic endothelium.⁷⁷ They are thought to occur in relation to the mesenteries of the stomach and spleen. Some of the lesions are considered to be malignant since they involve adjacent structures, such as the pancreas, liver and abdominal wall. The lesions are not autonomous because regression occurs when treatment is discontinued.^{72,75} Transplantation to another animal is unsuccessful unless the host is injected with estrogens.⁷⁷ If progesterone or testosterone⁷⁸ or desoxycorticosterone acetate⁷⁹ is injected simultaneously with the estrogens, the tumors fail to appear. The initiation of uterine myomas in the guinea pig is therefore a good example of a species susceptibility to tumor formation.

Tumors of Pituitary Gland

Spontaneous tumors of the hypophysis seldom occur in mice or rats. In 1936, three groups of investigators⁸⁰⁻⁸² reported hypertrophy of the pituitary gland and the formation of chromophobe adenomas in mice and rats of both sexes after continued treatment with estrogens. These adenomas may be transplanted to other animals of the same strain, particularly when the host is treated with estrogen.⁸² Transplanted adenomas of the intermediate lobe of the pituitary gland in rats have also been observed after estrogen therapy.⁸³ These various changes do not

occur in all strains of the same species, which demonstrates again the importance of a specific susceptibility to tumor formation. A more detailed review of the subject was recently written by Selye.⁸⁴

Tumors of Testis

Teratomas of the testes of the fowl have appeared after the injection of zinc chloride.⁸⁵ In most cases the tumors arose in the spring when spermatogenesis begins, but tumors have likewise been produced in the summer when extracts of the anterior pituitary gland of sheep were injected in combination with zinc chloride.⁸⁶ It has been postulated that the tumors arise from the primary germ cells as a result of stimulation of the gonocytes by gonadotropic hormones.⁸⁷ Seminomas have appeared after partial gonadectomy,⁸⁸ in which case, as the gland regenerated, the spermatogonia went on to tumor formation instead of undergoing normal differentiation. This effect was ascribed to excessive secretion of the gonadotropic hormones as a result of the partial castration, a state that may also arise after necrosis produced by zinc chloride injections. Although the evidence is not conclusive for a hormonal origin, there appears to be a common denominator. All three methods of tumor production, apparently, are related to increased stimulation of the gonads by the gonadotropins.

The production of interstitial cell tumors of the testes in certain strains of mice by the injection of estrogens⁸⁹⁻⁹¹ suggests a more definite hormonal relation. Simultaneous injection of testosterone at a certain dose level does not prevent the appearance of tumors, but the rate of change is retarded.⁹² In the sequence of events leading up to the development of these tumors, progressive phases of atypical cells appear with atrophy of the tubules. This is manifested by the formation of three generations of Leydig cells. Tumors may arise from any one generation or from a combination of two or of all three generations of cells.⁹² These tumors appear malignant and metastasize widely, particularly to the lymph nodes.⁹⁰ Transplantation to other animals is successful when the host is treated with estrogen.⁹² Long-continued injections of equine gonadotropins elicited changes in the testes of certain mice that resembled those seen in the early stages of the tumors developed by estrogens.⁹³ Thus, as in the case of the fowl tumors, the gonadotropic hormones may be responsible for the changes. Many of the tumors appear to function, since the seminal vesicles and prostate of the animals exhibited an androgen effect.⁹⁰ Tumors of this type produced by any form of estrogen appear to be species limited as well as strain limited. Like cancer of the mammary gland and cervix in the mouse, the tumors arise only after prolonged treatment and after the tissue fails to respond in the usual fashion, or has regressed.¹²

Tumors of Adrenal Gland

Tumors of the adrenal gland in mice are exceedingly rare, but a technic devised by Woolley, Fekete and Little^{7,8,94} has resulted in the production of many of these lesions. A variety of changes appear in these glands subsequent to castration in both sexes during the first days of life. The development of the different types of lesions depends to a great degree on the strain used. In one strain, slight hyperplasia occurs, whereas in another, all the mice develop adrenal hyperplasia, nodular or diffuse, which is accompanied by feminization of both sexes.⁸ Cancer of the breast may occur in these animals, presumably as a result of estrogenic substances secreted by the adrenal glands. All the animals of a third strain develop adrenocortical carcinoma at about one year of age.⁹⁵ Early in the development of the process, before true carcinoma appears, there may be an accompanying feminization, but masculinization appears with the onset of carcinoma. The tumors originate in the outer zones of the cortex, and the transitions from hyperplasia to carcinoma and from a feminization to masculinization can be easily followed.⁹⁵ Studies of the excretion of estrogenic hormone in the urine of mice with adrenal hyperplasia reveal about six times as much as is found in control animals.⁹⁶

Lymphoid Tumors

Lymphoid tumors and leukemia arise spontaneously in some strains of mice and rats, and in general there is a higher incidence in the male. Injection of estrogens into any strain of mice that has a tendency to develop these lesions results in an increased incidence of the diseases,⁹⁷⁻⁹⁹ and the incidence can also be raised by treatment with carcinogenic agents or x-ray.^{100,101} As in mammary carcinoma, the milk influence seems to be necessary in the genesis of these lesions.¹⁰² The lesions are usually widespread and can be easily transplanted. Murphy and Sturm¹⁰³ reported that removal of the adrenal glands greatly increases the susceptibility of rats to a transplanted lymphatic leukemia. They also found that the injection of adrenotropic hormone, adrenocortical extract and desoxycorticosterone acetate effectively reduced the percentage of "takes" of transplanted leukemic tissue.¹⁰⁴ No effect could be demonstrated on the eventual progress of the disease if the transplants were successful. Castration of the male in one strain of mice increased the incidence of the leukemia to that of the untreated female. Ovariectomy in the female in the same strain had no effect on the incidence of leukemia. Injection of testosterone in the ovariectomized female reduced the incidence to that of the untreated males.¹⁰⁵ In another study the incidence of leukemia in the female was reduced after ovariectomy but orchidectomy in the male had no effect.¹⁰⁶ Although there is some difference between these two studies, the age at castration

may have been a factor. Heilman and Endel¹⁰⁷ noted temporary retardation of the growth of transplanted leukemia after the administration of Compound E. After a time, however, the lesions became refractory and resulted in the death of the animal.

Tumors of Prostate Gland

Enlargement of the prostate gland occurs in about 80 per cent of dogs above the age of about 8 years.¹⁰⁸ Huggins and his collaborators¹⁰⁹ demonstrated that androgens given to the dog increased prostatic secretion and produced hyperplasia of the epithelial cells. Metaplasia occurred in some animals, and simulated the histologic appearance of cancer. Castration or injection of estrogens caused regression of the metaplasia and inhibited the production of prostatic fluid. Estrogens in themselves produce enlargement of the prostatic gland in the dog, which regresses when treatment is discontinued. On the other hand, continuous injection over a long period brings about squamous metaplasia of part of the epithelium of the prostate gland of the mouse.^{110,111,112} A similar change can be effected in the rhesus monkey.^{113,114} The atypical effects do not occur when testosterone or progesterone is injected simultaneously with estrogens.^{115,116} In rabbits, estrogen injection causes squamous metaplasia of the urethra around the orifice of the seminal vesicle.¹⁰⁸ Estrogens also cause hypertrophy of the seminal vesicles of mice. In no species of animal, however, has carcinoma of the prostate been produced by the administration of either androgen or estrogen. This is of interest in light of the recent observations regarding the relation of these hormones to cancer of the prostate in man. It appears that both hormones act on the prostate gland but in an entirely different fashion.

Other Tumors

Spindle-cell sarcomas have been reported in mice and rats at the site of injection of estrogens in oil.¹¹⁷ These have also appeared, however, after the injection of other substances other than estrogens that were dissolved in oil.¹¹⁸ They have not been observed when pellets of estrogens have been implanted.¹¹⁹ Osteogenic tumors have been reported as occurring in one strain of mice.¹¹⁹ Both osteosarcoma and osteogenic sarcomas were observed and were frequently multiple.¹²⁰ Approximately 75 per cent of the females and 25 per cent of the males develop these lesions on an average of one and a half years of age, the females developing the tumors somewhat earlier than the males.¹¹⁹ Injections of estrogens increased the incidence in males and decreased the age at which the tumors appeared in both sexes.¹²¹

Summary

A wide variety of tumors can be produced and altered in the experimental animal, but these a

endent on the species, the strain and the individual susceptibility of the animal and there seems to be some limiting factor in the proportion of tumors in animals in which attempts have been unsuccessful. Consequently, it is difficult to translate these observations to the study of human cancer. They are, however, of great importance as a tool in the study of oncogenesis in general.

(To be concluded)

BENJAMIN CASTLEMAN, M.D., *Acting Editor*

EDITH E. PARRIS, *Assistant Editor*

CASE 30491

PRESENTATION OF CASE

An eighteen-year-old-girl, a student, was admitted to the hospital with diarrhea.

Nine years prior to admission, at the age of nine, the patient first noted mild diarrhea with two to three soft stools a day. This gradually grew worse over a period of years until two and a half years before entry, at which time she had a sudden increase in the diarrhea, with many watery stools daily, which never contained blood. This was associated with anorexia, nausea, vomiting, discomfort in the right upper quadrant, generalized malaise and some fever. These symptoms were presently followed by deep jaundice. She was treated at a local hospital, where a diagnosis of catarrhal jaundice was made. She remained in the hospital several weeks, and the jaundice disappeared. Following this episode she had a partial remission of diarrhea for about a year. One and a half years prior to admission she developed nasal catarrh associated with fever. During this episode the diarrhea became worse and some blood streaking in the stools was noted; there was no jaundice. The diarrhea showed several remissions and exacerbations, with frequent blood streaking. About five months before admission, a small amount of sugar was found in the urine, and a physician placed her on a strict diabetic diet without insulin. No blood sugar determinations were done at that time. She had considerable anorexia and lost about 35 pounds in four months. The diarrhea continued and was associated with marked tenesmus. Two weeks prior to entry a blood sugar was done at another hospital and was found to be 80 mg. per 100 cc. Because of the persistent diarrhea, an ileostomy was recommended. Five days before entrance into this hospital the diarrhea increased, there being fifteen to twenty watery stools daily, with some blood clots. She developed fatigue, lassitude, drowsiness and a craving for salt and water.

The past history was noncontributory. The patient's mother and her grandfather, aunt and uncle on her mother's side all had diabetes mellitus.

*On leave of absence.

Physical examination revealed a pale, emaciated young girl appearing acutely ill and dehydrated. There was marked clubbing of the fingers. The heart appeared slightly enlarged to the left, and there was a soft blowing systolic murmur over the pulmonic area, which disappeared on inspiration. The abdomen was tender, without spasm. A definitely spastic colon was palpable.

The temperature was 101.4°F., the pulse 136, and the respirations 24. The blood pressure was 120 systolic, 55 diastolic.

Examination of the blood showed a red-cell count of 3,550,000, with 10 gm. of hemoglobin. The white-cell count was 8400, with 73 per cent neutrophils, 26 per cent lymphocytes and 1 per cent monocytes. A catheterized urine specimen had a specific gravity of 1.018, with no albumin or sugar; a few white cells were seen in the sediment. The stool was grossly bloody, with clots. The blood sugar was 95 mg. per 100 cc. The serum nonprotein nitrogen was 23 mg. per 100 cc., the chloride 94 milliequiv. per liter, and the protein 4.95 gm. per 100 cc., with an albumin-globulin ratio of 0.93. The prothrombin time was 33 seconds (normal, 18 to 20 seconds). A urine culture was sterile. A blood Hinton test was negative.

Röntgenograms of the chest and abdomen revealed only some increase in lung markings and a diffuse haziness of the abdomen, suggesting an accumulation of fluid.

The patient's temperature ranged between 100 and 102°F. There was apparently some transient jaundice on the first hospital day, but none thereafter. She was given numerous transfusions of whole blood and plasma, together with intravenous saline solution, Amigen and vitamins, as well as sulfadiazine. On the second hospital day, following a plasma infusion, she developed a chill, with a rise in temperature to 103.6°F. and some vomiting. A blood culture taken at the time was negative. On the following day marked ankle edema was noted, together with basal rales. The serum protein at that time was 4.4 gm. per 100 cc., with a chloride of 92 milliequiv. and a sodium of 128.3 milliequiv. per liter. On the seventh hospital day, proctoscopy revealed an extremely friable bleeding mucosa with a granular and edematous appearance but no frank ulceration. This was thought to be compatible with an acute ulcerative colitis. A stool smear showed no cysts, and there were many red and white cells present. The following day an ileostomy was performed, and examination of a small piece of ileum revealed acute and chronic inflammation with ulceration. At the time of operation about a liter of ascitic fluid was removed.

Following the operation, the temperature rose to 104.5°F., and the edema increased, with distended neck veins, a rapid pulse and slow gasping respirations. The heart was found to be enlarged to the left, and there were moist rales at the bases of the

lungs. At that time the serum protein was 4.97 gm. per 100 cc., with an albumin-globulin ratio of 0.8; the chloride was 91.4 milliequiv. per liter, the prothrombin time 44 seconds (normal, 18 to 20 seconds) and the van den Bergh 3.3 mg. direct, and 8.4 mg. indirect.

The patient was given oxygen and digitalized. She was also given 25 per cent albumin intravenously, as well as plasma and whole blood. She was disoriented, was only slightly responsive and developed a high-pitched cry. No reflexes could be obtained in either the upper or lower extremities. The patient rallied somewhat following the intravenous therapy, the edema decreased, and she became more responsive. On the tenth hospital day aspiration of the stomach by a Levine tube revealed dark-brown fluid that gave a ++ guaiac reaction. The following day the patient suddenly became pulseless and expired.

DIFFERENTIAL DIAGNOSIS

DR. EARLE M. CHAPMAN: We are presented with a diagnosis of what was wrong with this patient. It says in the abstract that the patient had acute ulcerative colitis. At operation the surgeon removed a bit of ileum, which was said to show acute and chronic inflammation with ulceration. So as a starting point I think that we have to accept the fact that this patient had colitis and ileitis. But the problem is to explain why an eighteen-year-old girl should have had diarrhea for nine years and then die of the diarrhea. I do not believe that she had only ulcerative colitis and ileitis. There must have been a more deep-seated disease to explain this picture. In the analysis of the situation it comes down to a discussion of what causes prolonged diarrhea in young people.

First we have to consider that this might have been gastrogenous in origin. There is no statement concerning the results of a gastric analysis, but I cannot conceive that lack of hydrochloric acid could have explained this situation, although we know that in old people achlorhydria can cause prolonged diarrhea.

In regard to the colon, we are presented with a statement that she had ulcerative colitis, and although I think that this was not true idiopathic ulcerative colitis, we are not favored with reports of x-ray examination of the bowel to see whether ulcerations were present.

I see Dr. Logan Roots, of China, in the audience; he might suggest that this sounds almost like cholera. There are certain symptoms, such as the craving for salt and water, that suggest that diagnosis. I do not believe, however, that the diarrhea was caused by a bacterial infection.

We have, of course, to consider pancreatic disease as a source for diarrhea, and there I think we are

getting a little warmer in this case, because we know that there was a disordered pancreas in the family background. If she had a disordered pancreas, what was the type? The laboratory data are of no help to us, because if she had sprue we should have a better description of the stools, which I should expect to be described as foul, grayish and fatty containing; but nothing is said except that the stools were thin and watery and finally contained blood.

DR. BENJAMIN CASTLEMAN: They were not fatty.

DR. CHAPMAN: Another disorder of the pancreas that can lead to this picture and give stools of that character is Chiari's disease.¹ He described four conditions in the pancreas that can cause a disturbance of this sort: cystic degeneration; fibrosis; a condition that is rather unusual, phlebitis of thrombosis in the venules in the pancreas; and hemorrhage and necrosis.

I was interested to note that she had clubbing of the fingers. Why should her fingers be clubbed? X-ray films of the chest did not point to pulmonary disease, although it says there was "slight increase of the lung markings." Andersen and his associates² have described cystic degeneration of the pancreas associated with bronchiectasis in the lung, and diarrhea was a prominent feature of the disease. Might she have had this syndrome? There is nothing in the evidence to support it, but one certainly has to mention it.

The last condition to consider is disease of the liver. There are facts in the story that point to primary liver disease in this patient. We know that two and a half years before entry she had anorexia, nausea, vomiting and discomfort in the right upper quadrant, which is anatomically the region of the liver. Following this she had what was said to be "catarrhal jaundice" and thereafter went downhill. In addition, sugar appeared in the urine. Liver disease commonly causes a disturbance in glucose metabolism and has been confused with diabetes mellitus. In further support of liver disease is the low total protein and the high prothrombin time. It is too bad that a cephalin flocculation test or some other test of liver dysfunction was not done. This matter of jaundice appearing and going away is quite surprising, but she must have continued to have jaundice because later the van den Bergh test was 3.3 mg. direct and 8.4 mg. indirect.

If this patient did have some kind of liver trouble, what was the type? It certainly was not portal cirrhosis. Did she have biliary cirrhosis? I cannot say. There is no evidence to support that diagnosis. She did not have a palpable spleen or a big liver, but she did have ascites, and when she was given fluids, she even developed edema. The description of death in the last paragraph sounds to me like that of a patient dying in cholemia.

here is one other rare disease that should be mentioned, another Chiari's³ disease, not in the creas but in the liver, — I have been fooled by once before here,⁴ — that is, a thrombophlebitis of the liver venules themselves. It is a most bizarre nature and is usually seen in older people with carcinoma. This was a young girl, so that we do not suspect carcinoma.

In conclusion, I am forced to make one choice. I have mentioned five possibilities in their increasing order of likelihood. I am going to end up with the final choice that this patient had some type of liver disease, probably Chiari's syndrome. Possibly she had a combination of two of his syndromes, not only a thrombophlebitis of the pancreas but also a peculiar type of cirrhosis following thrombophlebitis of the liver venules. It would not surprise me if she also had bronchiectasis.

DR. FRANCIS D. MOORE: The patient entered on the medical service and was seen in consultation by the surgical service. Most of us lacked Dr. Chapman's diagnostic acumen and were not convinced that there was any pre-existing pathologic process. Her general appearance was thoroughly compatible with one of the extremely sick patients with ulcerative colitis. Clubbing of the fingers has been a repeated observation in ulcerative colitis. This girl had less ascites than some patients with ulcerative colitis. When present, it must be due to the fact that the whole colon is involved as a single tubular abscess and the permeability of the capillaries is increased, so that they pour fluid out into the abdomen as well as into the bowel. She had an ileostomy, and it is routine to resect 1 or 2 cm. of ileum, between clamps, and send it to the Pathology Department to determine whether the disease has extended into the ileum, which is a gloomy prognostic sign. This girl did have ulceration there. The story from there on is up to Dr. Castleman.

CLINICAL DIAGNOSES

Chronic ulcerative colitis and ileitis.
Cardiovascular collapse
Operation: ileostomy.

DR. CHAPMAN'S DIAGNOSES

Ulcerative colitis and ileitis.
Liver disease (? Chiari's syndrome).
Cholemia.
Bronchiectasis?

ANATOMICAL DIAGNOSES

Ulcerative colitis, involving entire colon and distal ileum.
Acute hemorrhagic hepatitis, superimposed on toxic cirrhosis.
Fatty vacuolization of liver, severe.
Operation: terminal ileostomy.
Splenomegaly.

Hemorrhage from mucosal and serosal membranes.
Ascites.
Pulmonary edema and congestion.
Anasarca.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The autopsy on this girl showed an extremely acute, as well as a chronic, ulcerative colitis involving the entire colon and the lower 75 cm. of the ileum. There were numerous ulcers, both longitudinal and transverse, without any bridging such as one sees in the more chronic stages, but there was a lot of edema in both the mucosa and the wall. Microscopic sections confirmed a non-specific acute ulcerative process. We looked hard for amebas but could not find any. The appearance was not inconsistent with what we see in other cases of ulcerative colitis, but as Dr. Chapman implied, that was not the whole story, and he rightly cited the liver as one of the sources of her trouble. The liver presented a striking appearance. Although it was normal in size, weighing 1500 gm., it was composed of bright-yellow fatty irregular nodules, each apparently surrounded by a deep red cuff (Fig. 1). At first we thought that this was a characteristic acute and subacute yellow atrophy of the liver and that these yellow areas were areas of regeneration, the rest being areas of frank necrosis. It would be a little unusual, however, for a person with that amount of necrosis — although there was a lot of regeneration — not to have had more jaundice. Most patients with subacute yellow atrophy are severely jaundiced. Microscopically these nodules were areas of regeneration with extreme fatty vacuolization. The nodules were surrounded by fairly dense connective tissue in which there was extensive hemorrhage.

We know that in ulcerative colitis the almost constant finding at autopsy is a marked fatty vacuolization of the liver, and we can explain all these fatty changes within the regenerated liver nodules as having been due to ulcerative colitis. So this is an example of a healed atrophy type of cirrhosis, the acute attack probably having occurred two and a half years before entry, when she was sick for two and a half to three months. At that time a fair amount of liver tissue was destroyed, this being followed by regeneration. She had recently developed an acute hemorrhagic process of the liver that had little effect on the regenerated nodules. It is quite possible, as has been shown by MacNider⁵ experimentally, that regenerated liver cells are more resistant to another toxic attack than are normal liver cells. Perhaps the ulcerative colitis was just a manifestation of the liver disease. We have never seen it so severe as this, but some of the cases of epidemic jaundice that are now being seen in the Army have shown marked edema and inflammation of the colon.⁶ I should think that it is fair to assume

that the fundamental disease nine years before entry was ulcerative colitis, that two and a half years before entry the patient developed liver disease and that perhaps the toxins derived from the ulcerative colitis produced this further liver damage.

FIGURE 1. Photograph of Liver

DR. FULLER ALBRIGHT. The veins were all right?

DR. CASTLEMAN: It was not Chiari's syndrome.

DR. MOORE: It is interesting that during the same week that this patient died Dr Altschule and his associates,⁷ of the Beth Israel Hospital, reported the cases of 16 or 18 patients who had had catarrhal jaundice at various periods of time up to many years previously. They had subclinical jaundice, as evidenced by an elevated van den Bergh, and it is interesting that of this small group, two had chronic diarrhea and one had frank ulcerative colitis.

DR. CASTLEMAN: I suppose it is possible that the cirrhosis went back more than two and a half years and that the first attack of diarrhea nine years before entry resulted from hepatic disease. I do not know any way of telling, however.

DR. WILLIAM B. BECKMAN: We had a patient with primary liver disease who during the last six or eight weeks of life developed severe ulcerative colitis. We never knew what kind of liver disease it was.

DR. CASTLEMAN: It is striking that Lucké,⁶ who worked up the cases of epidemic jaundice for the Army, had a number with involvement of the colon.

CASE 30492

PRESENTATION OF CASE

A fifty-one-year-old housewife was admitted to the hospital because of a productive cough.

Six months prior to admission the patient noted a tickling sensation in her throat that caused her to cough and raise sputum. This increased until she was raising about half a cupful of thick green sputum daily, most of it in the morning. During this period she had lost 10 pounds in weight, and noted diminished vigor. Some tenderness was present over the right lower chest. There was no hemoptysis, night sweats, fever or dyspnea.

Two months before entry a roentgenogram of the chest was taken by a physician who recom-

ended a bronchoscopy. This was performed two weeks before admission, and she was told that she had "congestion" in her lungs. She was referred to the hospital for further study.

The patient had had a cholecystectomy twenty years previously. Two months before entrance into the hospital a tumor of the right breast, apparently without sign, had been removed.

Physical examination on admission revealed a well-developed, well-nourished woman, not acutely ill.

The lower anterior portion of the right chest

size, but the interlobar septum between the upper and middle lobes was slightly low. A Bucky film revealed the trachea to be normal, and its bifurcation and both main bronchi were well outlined. The lower lobe bronchus could not be followed beyond the mass. An intravenous pyelogram showed prompt dye excretion and normal calyces, pelves and ureters. There was evidence of considerable pressure on the bladder, particularly on the right, but no definite soft-tissue mass was visible and the organ emptied normally.

FIGURE 1. Roentgenogram of Chest.

was tender and dull to percussion, with many moist and crackling rales. A small umbilical hernia was present, and there were marked varicosities of the veins of the lower extremities.

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 80 diastolic.

Examination of the urine was essentially negative. A blood Hinton test was negative.

A roentgenogram of the chest revealed an ovoid area of increased density measuring 7 by 4.3 cm., lying across the right lower lung field in the region of the lower lobe (Fig. 1). It was outlined fairly sharply and contained a fluid level. Areas of calcification were present along the lower margin of the mass. The heart and mediastinum were displaced slightly to the right. The remainder of the lung fields was clear. In the lateral view the right lower lobe did not appear to be much reduced in

A bronchoscopy on the second hospital day revealed considerable grayish-white, rather sticky secretion throughout the right bronchial tree. The bronchus of the right lower lobe was reddened and a little edematous, but there was no narrowing. The findings were thought to be consistent with chronic bronchitis.

On the ninth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. LAURENCE L. ROBBINS: I shall not attempt to discuss this case from the clinical standpoint. The roentgenologist is usually asked to examine the patient, make up his mind concerning what the fundamental process is and then use the clinical evidence to arrive at a diagnosis. Consequently let us go at this purely from the roentgenologic approach. Let us look at the intravenous pyelogram

and try to eliminate the urinary tract, because I am going to spend most of the time on the chest findings. So far as I can see, the kidney shadows are normal. There is perhaps a questionable mass in the pelvis, but nothing definite except evidence of pressure on the superior surface of the bladder. So far as the bones are concerned they appear normal for the patient's age, except for some degenerative changes around the lumbosacral joint, and in some films there is a questionable defect in the lateral masses of the fifth lumbar vertebra, which suggests that the patient may have had a spondylolisthesis. I shall discard what goes on in the abdomen. It is going to be embarrassing if the operation on this patient turns out to be abdominal, but I can see nothing from the x-ray standpoint that indicates interference in that part of the body.

The films of the chest show an ovoid lesion. To approach it from an anatomic standpoint, where is this lesion? It appears to be fairly well surrounded by air but extends rather close to the pleura posteriorly. It lies in the right lower lobe, probably in the posterolateral division of this lobe. What are the other features of this mass? It is fairly smooth in outline, contains fluid and air, and in the lower margin of the mass there appear to be flecks of calcification. The wall of the mass is thin, although we do not know whether that is true regarding the entire circumference. Fluoroscopy would be helpful because one could tilt the patient from one side to the other to change the level of fluid and thereby get a better view of the wall.

What else is going on within this lobe? Perhaps it is a little smaller than usual, and I think that the septum between the middle and the lower lobes lies farther posterior than is the usual finding. Also, some of the bronchi are perhaps slightly dilated.

In regard to differential diagnosis, the first question is, Is this a tumor? Yes, it could be a primary tumor that had become necrotic in the center and was draining through a bronchus. One factor against that is the rather thin wall, and where we are able to visualize it, the lesion appears to be fairly smooth in outline. Could it be metastatic tumor from carcinoma or sarcoma elsewhere? Yes, but it is rather rare for metastatic lesions to break down and drain into a bronchus. Could it be a lymphoma? Lymphoma of the lung is relatively rare, and in the few cases that I have seen, it has not broken down; nor have I seen calcification within it. That more or less covers the group of tumors. I cannot completely rule out carcinoma, but it does not seem likely.

Could it be a tuberculoma? It is in the lower lobe, and in the few cases that we have seen the majority of the lesions have been in the upper lobe. The calcification would go with tuberculoma. We shall have to wait and see if we can find anything in the clinical findings that will be of help.

Could it be an abscess? If it were an abscess, I should think that it would be on the basis of inhalation or associated with bronchiectasis. The calcification in the wall could go with long-standing abscess, and the rather thin wall could again go with it, because it would mean that the abscess had been present for a long time, developed a capsule and was well localized. I do not believe that it was an abscess on the basis of a septic infarct because that usually clears in a relatively short time, and in the cases that we have seen they have not localized quite so well as this.

Then we come to the possibility of bronchiogenic cyst, or what is often called a "hamartoma." So far as I can gather, the difference between a true bronchiogenic cyst and a hamartoma is essentially that the cyst contains more glandular material within it and secretes the mucoid material that is so characteristically found in these cysts. It certainly could be a bronchiogenic cyst that had become necrotic and was draining through a bronchus. I do not believe that the calcification within the wall is against such a diagnosis.

I have covered the x-ray examinations fairly thoroughly, and in general my interpretation has not varied greatly from the original one. Now let us turn to the clinical findings to see if we can get any further information. We have the story of a patient raising large amounts of sputum, which is consistent with bronchiectasis or an abscess or a bronchiogenic cyst that had become infected and drained into a bronchus. I still cannot rule out necrotic tumor, but there is no evidence of hemoptysis, which is of considerable importance. A previous x-ray examination for comparison would be a tremendous help. We do not have that by any chance?

DR. BENJAMIN CASTLEMAN: No.

DR. ROBBINS: In the past history we find that the gall bladder and a tumor of the right breast had been removed, which raises the remote possibility of metastatic tumor. But for the reasons that I have given we shall disregard that diagnosis. It is difficult to explain the physical findings entirely by the lesion in the chest. There is, however, a shadow in the anterior costophrenic angle that may or may not be of significance. The number of things that it could be in that area are legion, and I am not going to get mixed up in a discussion of them. So we come down to the fact that this patient had had a six-month story of raising fairly large amounts of sputum in the morning. I cannot take a definite stand and say whether this was due to a lung abscess, tuberculoma or infected bronchiogenic cyst, but I am inclined to put the most emphasis on a long-standing lung abscess, even though the history does not exactly fit in with it, and put as my second choice an infected bronchiogenic cyst.

DR. CASTLEMAN: Are there any further questions?

DR. HELEN S. PITTMAN: I should put abscess first on the list. I think that it is surprising, however, that it was an abscess, that the patient had no fever and no elevated white-cell count. There is no mention of the sputum. If it were an abscess, I would expect the sputum to be unpleasant enough so that there would have been a note about it somewhere.

DR. RALPH ADAMS: I believe that it was a bronchiogenic cyst, not a chronic lung abscess and not a malignant tumor with central necrosis. It seems to me that a lung abscess of six months' duration would have had a wall that was thicker than the apparently thin wall in this case. Furthermore, the sputum in a lung abscess with the amount of sputum that she would, almost certainly, have been foul and very likely would have been bloody. The tumors with central necrosis have, by and large, the so-called "sore thumb" sign. One sees air at the top of the cyst and a suggestion of fluid level, but here it is piling up in the center, which has come to be recognized as the tumor seen in profile. In addition, a malignant tumor, particularly if it is breaking down, almost always causes hemoptysis. For these reasons I think that the lesion was a bronchiogenic cyst.

CLINICAL DIAGNOSIS

Bronchiogenic cyst.

DR. ROBBINS'S DIAGNOSIS

Lung abscess?

Bronchiogenic cyst, infected?

ANATOMICAL DIAGNOSES

Lung abscesses.

Bronchiectasis.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The patient was operated on and the right lower lobe was removed. There were no adhesions over the surface of the lung, and apparently the surgical procedure was not particularly difficult. We were able to feel a hard mass within the lobe, and the surgeon, before removing the lobe and therefore before the surrounding lung had collapsed, reported that the mass was extremely hard; because of this and because he was unable to feel any fluctuation, he toyed with the idea that it was a tumor.

After fixation the lung was sectioned. In the central portion of the lobe we were able to find three cavities, two communicating with each other, but separate from the others. They all communicated with a major bronchus (Fig. 2). The walls were thin, measuring only 1 mm. in thickness

in most places. The inner surfaces of these cavities were granular, and microscopic studies showed no evidence of tuberculosis. All the cavities were lined by bronchial mucosa, and I therefore believe that they were abscesses, perhaps bronchiectatic, rather than bronchiogenic cysts. I do not suppose there is any real way of proving this except that the walls were exactly like that of a bronchus. One did not have to hunt for the various bronchial elements in

FIGURE 2 Photograph of Resected Right Lower Lobe.

the wall as one usually does in bronchiogenic cyst. Whether this was a bronchiectasis with abscess formation or whether it started out as an abscess and secondary bronchiectasis developed I do not believe that anyone can say. The fact that there was no involvement of other bronchi is suggestive that it started as an abscess, which later communicated with a bronchus. That there were three of them is also in favor of their being abscesses.

THE CHRISTMAS SEAL CAMPAIGN

THE seriousness of the tuberculosis problem is strikingly shown by statistics recently issued by the National Tuberculosis Association. One out of every hundred men examined for military service has been disqualified by having the disease — 30 per cent showing it in a clinically active form. Furthermore, in the thirty-one months after Pearl Harbor the deaths from tuberculosis in the United States were nearly three times those occurring in combat — 145,000 against 57,000.

Although the tuberculosis death rate has been reduced 75 per cent in the last forty years, its ravages continue, in spite of the fact that the means of prevention and cure are well established. Fifty-six thousand people in this country died of tuber-

culosis last year, and it is estimated that over a million people have the disease, only half of them being known cases. In the war-torn countries of Europe the problem is, of course, ever so much more serious. In the United States, indications point to a reversal of the downward trend of mortality unless drastic steps are taken to prevent it.

These facts give special importance to the approaching Christmas Seal Campaign. The fund thus raised will be devoted to widely publicizing x-ray examinations of the chest, to the follow-up and treatment of cases thus discovered and to many kindred activities in the fight against tuberculosis. In buying Christmas Seals to the limit of our resources, we shall not only be aiding in a domestic war but in no small measure be contributing toward the military victory that is sure to come.

THE FAT OF THE LAND

SINCE the strict rationing of 40 per cent cream went into effect on August 1, a monthly saving of 2,300,000 pounds of butter fat has been effected in the sixteen federal market areas, according to advices from the War Food Administration. In the face of such startlingly good results from a program that has been none too popular, although ostensibly designed to increase the amount of butter available to the consumer, the rise in the point value of the commodity to the almost prohibitive level of twenty points per pound is unfortunate and is hard to explain to the little people who are supposed to constitute the backbone of the nation. The explanation, however, has been made in a recent broadcast of Mr. John H. Sullivan, district director of distribution of the War Food Administration.

The first reason for the current butter shortage according to Mr. Sullivan, is that the current butter production is 17 per cent lower than the 1935-1939 average. A second reason is that we are sharing our supplies with both American and Allied fighting men. A third is that more people can afford to buy butter than ever before, because wartime incomes are higher; and a fourth, that the increased milk output is not going into butter but

other uses. Civilians, for instance, are drinking from 20 to 25 per cent more milk than formerly, and the armed forces have asked the manufacturers for evaporated and condensed milk for a 75 per cent increase in these products over last year.

Despite a 14 per cent increase in milk production since the years before the war, butter production, it has been indicated, has fallen off 17 per cent. Of the butter manufactured, 80 per cent of the total is available to civilians. 15 per cent is set aside for military purposes, and 5 per cent goes to Russia for use in military hospitals. The average civilian share will be something less than twelve pounds per person this year, as compared with nearly seventeen pounds between the years 1935 and 1939.

It is a poor American, indeed, who will not make enlightened sacrifices to help in winning the war, although he may still wonder why all but two and a half of his weekly red points are required to secure this allotted butter ration. Those of us who have seasoned our patriotism with philosophy, however, will continue cheerfully to do without heavy cream, and will learn that oleomargarine is an excellent substitute for the theoretical twelve pounds of butter.

MASSACHUSETTS MEDICAL SOCIETY

COMMITTEE ON POSTWAR PLANNING

The first meeting of the Committee on Postwar Planning, appointed by the President of the Massachusetts Medical Society, was held on November 8 with twenty-three members present. Important topics considered for committee action included the problem of providing both short-term and long-term residencies and refresher courses to medical men returning from service, the place of the hospital in postwar education, opportunities for doctors in public health and the relation of medicine to changing economic conditions.

The Committee begs the interest and co-operation of the members of the Society and asks that questions be sent to the chairman. Information bureaus at the headquarters of the American Medical Association and, for Massachusetts, at 8 Fenway, Boston, are expected to help physicians returning from service.

HOWARD F. ROOT, *Chairman*

DEATHS

BAUMAN — Julia L. Bauman, M.D., of Holyoke, died November 17. She was in her sixty-third year.

Dr. Bauman received her degree from the Women's Medical College of Pennsylvania. She was reputed to be the first woman of Polish birth to practice medicine in Massachusetts.

DRAPER — Frank E. Draper, M.D., of Framingham, died November 24. He was in his eighty-first year.

Dr. Draper received his degree from Harvard Medical School and studied at Vienna University. He was formerly assistant ophthalmic surgeon at the Massachusetts General Hospital and the Boston Dispensary and clinical assistant at the Massachusetts Eye and Ear Infirmary. He was a member of the New England Ophthalmological Society. He served as a captain in the Army Medical Corps during World War I.

His widow, a daughter, a granddaughter and a great granddaughter survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

USE OF DIPHTHERIA TOXOID IN ADULTS

Diphtheria toxoid is now the universally accepted agent for the immunization of children against diphtheria. It has been extensively used in adolescents and adults as well, but it is prone to cause marked reactions in a certain percentage of these unless small initial doses are used and subsequent doses are adjusted according to the presence or absence of a reaction to the first dose.

Since reactions to diphtheria toxoid in adolescents or adults are most frequent and severest in persons who are immune to diphtheria, it is of course essential that these be excluded from any immunization program by previous Schick testing. By taking this elementary precaution and by starting with a small initial dose (0.1 cc.) as indicated above, it is entirely practical to immunize adolescents or adults with diphtheria toxoid.

The practice of immunizing such persons with diphtheria toxin-antitoxin mixture has been abandoned almost everywhere, since toxin-antitoxin is less efficient than toxoid as an immunizing agent, and also because it necessarily contains serum from a horse or other animal. For these reasons, the use of toxin-antitoxin for individual immunization is no longer recommended, and the department will discontinue the distribution of the package containing three 1-cc. vials of toxin-antitoxin as of January 1, 1945.

Since the routine use of diphtheria toxoid in groups in which individual adjustment of the dosage is not practical is not as yet entirely satisfactory, toxin-antitoxin mixture in 20-cc. vials will continue to be furnished.

Interpretation of the Schick test. The usual instructions for interpreting this test state that subjects showing positive reactions with toxin and positive but smaller reactions with the control material are susceptible to diphtheria but are also sen-

sitive to the proteins of the diphtheria bacillus. Such persons are *exceedingly* likely to react either to toxin-antitoxin mixture or to toxoid, and should be immunized cautiously, if at all. Recent experience suggests that many such subjects are actually immune to diphtheria. Whenever there is doubt concerning the best immunizing procedure to follow, it is suggested that the person in charge consult the director of either the Division of Biologic Laboratories or the Division of Communicable Diseases regarding the advisability of determining the patient's serum antitoxin titer. This test which can be done in four or five days, is a valuable method for determining the patient's immunity. It can be carried out with 5 to 10 cc. of blood sent, preferably in a sterile tube, to the Antitoxin and Vaccine Laboratory.

BOOK REVIEW

Medical Clinics on Bone Diseases: A text and atlas. By I. Snapper, M.D. 4th, cloth, 225 pp., with 30 plates and 39 tables. New York: Interscience Publishers, Incorporated, 1943. \$10.75.

This monograph will prove stimulating to internists, surgeons, endocrinologists, roentgenologists and orthopedists. The author has had a wide experience in Amsterdam and later as professor of medicine at the Peiping Union Medical College in China, and he draws liberally from it in this critical review of recent concepts of certain of the bone disorders. The text is built around a group of the author's cases, which are given in considerable detail; the dissertation on each disease condition includes a discussion of the history, pathology, clinical symptomatology, biochemistry, pathologic physiology, differential diagnosis, etiology and treatment. A unique feature is the inclusion of photographic prints of the x-ray films, bound as full-page inserts with the text. As a result, the illustrations are decidedly superior to those usually found in reference books. An extensive bibliography is included at the end of each chapter; an author and a subject index are placed at the end of the monograph.

The author devotes half the monograph to a discussion of conditions associated with hyperfunction of the parathyroid glands, both primary and secondary. He discusses, among other topics, von Recklinghausen's observations, classic osteitis fibrosa cystica with gross bone involvement, renal complications of hyperparathyroidism, with and without involvement of the skeleton, gastrointestinal symptoms from hypercalcemia, differential diagnosis of hyperparathyroidism, and various phases of parathyroidectomy. Although the general discussion is excellent, the interpretation given to some of the investigations quoted from the literature are misleading and tend to undermine confidence in the rest of the work. Little discussion is made of the point that bone disease need not develop in patients with hyperparathyroidism if sufficient calcium and phosphorus are ingested in the diet; as a corollary to this, the author is reluctant to admit the existence of cases in which the only demonstrable pathology is in the renal system, although these are commonly found by physicians on the alert for them.

Hyperparathyroidism secondary to osteomalacia and chronic renal insufficiency are discussed. To the reviewer, this chapter seems rather confused. Although in an earlier section the author calls attention to the fact that acidosis induces osteitis fibrosa, he gives little consideration to acidosis as a cause of the bone lesions in the cases with chronic renal insufficiency; furthermore, he does not discuss the effect of correcting the acidosis on the bone lesions or on the abnormal calcium and phosphorus levels in the blood. He notes that some cases have hyperphosphatemia because of phosphate retention and that some cases have hypophosphatemia,

which he believes is due to osteomalacia from poor diet and lack of sunlight instead of hyperparathyroidism; does not discuss the hypocalcemia in these cases as a cause of excretion in the urine of calcium as a fixed base to the acidosis.

The author gives an interesting account of osteitis fibrosa as it is found in China, where poor diet and lack of exposure to sunlight combine to produce avitaminosis D. In the United States, however, osteomalacia is commonly seen only as a result of steatorrhea from such disorders as nontropical sprue or pancreatic disease; no discussion of these conditions is included. This section would also have profited from some consideration of the effect of vitamin D on calcium and phosphorus metabolism. Excellent chapters are included on Paget's disease of bone, Gaucher's disease and multiple myeloma. The illustrations and the cases in these sections are among the best in the monograph.

A detailed discussion is given of lipid granulomatosis or xanthomatosis of the bones. The author contends at length that osteitis fibrosa disseminata (Albright) or multiple fibrous dysplasia (Lichtenstein) is a manifestation of local granulomatosis of the bones, but his evidence is not convincing. He points out that lipid infiltration is a secondary process even in so-called "lipoid granulomatosis"; hence, secondary infiltration with lipid might reasonably be expected to occur in an occasional case of osteitis fibrosa disseminata. Furthermore, his insistence that lipid infiltration can be demonstrated only in a biopsy of a lesion is difficult to reconcile with lipid infiltration as a secondary process; that is, one would not expect to find it in the earliest lesions.

In the differential diagnosis of hyperparathyroidism, the author considers Paget's disease, multiple myeloma, generalized cancer metastases in the bones, decalcification of the bones in hyperthyroidism, lipid granulomatosis of the bones or xanthomatosis ossium (including osteitis fibrosa disseminata), chronic renal insufficiency and osteomalacia. One is disappointed not to find a discussion of sarcoidosis, lymphoma involving bone, benign metastasizing hemangiomas and osteoporosis. One would like also to have found included in this monograph some discussion of neurofibromatosis, osteopetrosis, the effect of lead and fluoride on bones, hyperparathyroidism and the various conditions causing tetany. The most surprising omission is osteoporosis. This condition, which is considered to result because of a defect in the formation of the matrix rather than in the calcification of it, is not clearly defined in the monograph. At times the author appears to be using osteoporosis as a general term for a rarefied bone. Osteoporosis has been found associated with immobilization and reduction in stress and strain, senility, postmenopausal state, Cushing's syndrome, hyperthyroidism and conditions associated with protein depletion (hunger osteopathy). Osteoporosis has been recognized as one of the commonest metabolic bone disorders, — postmenopausal osteoporosis, in particular, having been widely observed. The author barely mentions a few of these conditions. Exception must also be taken to certain statements. The author speaks of normal calcium and phosphorus metabolism when he means normal levels of calcium and phosphorus in the blood; he states that, in bone metastases from cancer of the prostate, acid phosphatase is constantly present when he means that it is usually elevated above the normal level.

In spite of these criticisms, most of which would be passed over by the casual reader, the monograph is a valuable contribution in a field largely unknown to most physicians. It should find considerable use as a reference work among persons interested in these disorders.

The publishers are to be commended on the mechanical features of the book: it has excellent illustrations, good type, substantial paper, sturdy binding and no typographical errors.

NOTICES

NEW ENGLAND ROENTGEN RAY SOCIETY

The next meeting of the New England Roentgen Ray Society will be held at the Harvard Club on Friday, December 15. There will be an x-ray conference at 4:30 p. m. At 8:00 p. m. Dr. Kurt H. Thoma will speak on the subject "Tumors of the Jaw."

SYMPOSIUM ON GALL-BLADDER DISEASE

A PLEA FOR THOUGHT-TAKING IN THE MEDICAL TREATMENT OF CHOLECYSTITIS*

WALTER C. ALVAREZ, M.D.

ROCHESTER, MINNESOTA

WHEN faced by a patient demanding medicine for a disease for which there is no known or logical treatment, the medical profession has always found it easier to give something than to try to explain why nothing is likely to cure or even to relieve the condition. Unfortunately, most patients will not even stop to listen to such frank speech; they believe firmly in the efficacy of medicine and diet, and they know that there are treatments available for every disease. If an honest physician refuses to give them treatment that he thinks is useless, they usually persist until they find someone who will give them a placebo of some kind.

At first glance this seems to be the best way out for all concerned, but actually it is hurtful to the physician, because after prescribing a placebo for a few years he is almost certain to forget that it never had any basis in scientific fact. He will come to believe in its efficacy, and if he is a writer, he is likely soon to be listing and even praising the medicine in his articles and textbooks. Then, if someone comes along who questions the logic of its use or its efficacy in practice, he is likely either to ignore the doubter or to become angry with him for his silly caviling.

Throughout the United States today the current medical treatment for cholecystitis is a diet low in fats and a prescription for some proprietary pill containing usually bile salts or bile salts with some cheap laxative, such as phenolphthalein. The two questions that should arise in one's mind are, How logical and scientific are these prescriptions, and do they do any good? In the first place, why should a person with a diseased gall bladder avoid fats? Originally the idea probably was that bile helps in the digestion of fats, and that hence when there is disease in the biliary tract fats should be avoided. Actually, in all cases of cholecystitis without jaun-

dice, the bile is flowing from the liver into the duodenum without hindrance, and in many cases the cholecystogram shows that the gall bladder is still doing fairly well in concentrating the bile. In other cases, the only defect is that in the intervals between meals the bile is not being stored properly in the gall bladder. In this event, it cannot be poured out in the usual concentration to meet the food when it enters the duodenum.

But if patients with cholecystitis frequently suffered from an imperfect digestion of fats, one would expect them often to have diarrhea with fatty stools and a progressive loss of weight, but this is not the case. Most of the patients suffer from constipation, and many digest so well that they gain in weight. My impression, gained from talking to scores of persons who have been on a low-fat diet, is that it did not make much difference in their digestive comfort. Many had a good digestion to begin with, and many of those who suffered with flatulence and a feeling of heaviness in the abdomen said that the secret of avoiding trouble was never to eat a *big meal* or a meal consisting of rich foods of any kind. A few had learned that certain foods like onions, cabbage or raw apples tended to cause trouble, and they had obtained some relief by leaving these foods alone.

Curiously, no one seems to have thought that the patient who has had a nonfunctioning gall bladder removed surgically is no different physiologically from what he was before the operation, and yet after the operation he is generally told to eat what he pleases, and he digests usually everything he eats. No one thinks of putting him on a diet. From this it must be concluded that the indigestion of cholecystitis is usually not due to any lack of concentrated bile in the upper part of the small intestine, and that hence there is no need of always barring fat from the diet.

Another reason sometimes given for the avoidance of fats in the diet of patients with cholecystitis is

*This paper and the two that follow were presented at the annual meeting of the Massachusetts Medical Society, Boston, May 24, 1944. From the Division of Medicine, Mayo Clinic.

that with a low intake of cholesterol the formation of gallstones may be avoided. There is no evidence in the literature that this precaution is worth taking, but granting that it is in some cases, it cannot be worth taking in the many cases in which the gall bladder is so packed with stones that it would be impossible to get any more in.

A diet sufficiently low in fats and carbohydrates can, of course, help by reducing the weight of the patient if he or she happens to be stout, but there is no reason for expecting this to restore a badly diseased gall bladder to a healthy state. According to some German writers, the restricted diet forced on Europeans by World War I cut down the frequency of colic in patients suffering from gallstones.

Interestingly, it has repeatedly been shown that if one wants to "flush out" the gall bladder by emptying it as thoroughly as possible, the best way to go about it is to give fats such as cream and egg yolk. According to Boyden, Sosman, Whitaker, and others,¹ fats cause the gall bladder to contract more forcibly and to empty more completely than does the magnesium sulfate that has so often been used for this purpose. To be logical, then, it seems that physicians should often be prescribing a diet rich in fats for patients with cholecystitis. To avoid fats in the diet is to invite stagnation of bile in the gall bladder. This favors excessive concentration of the bile, which in turn favors the formation of stones. The sensible thing to do is to have a patient restrict his intake of fat when a trial shows that this makes him more comfortable.

The pill containing bile acids is probably given with the idea that these substances will cause the bile to flow faster, that with this there will be a flushing out of the gall bladder, and that with the flushing there will be a clearing away of infection, and perhaps some washing out of small stones. According to Phibbs, Wigodsky and Ivy,² several investigators, among them Taterka, Impallomani and Jankelson and Altman,³ found that the giving of bile salts results in an increase in the size of the gall bladder, which indicates that with the more rapid flow of bile out of the liver there is an increase in the flow into the gall bladder. That there is no great increase in the flow out of the gall bladder and therefore no flushing effect with bile acids was shown by Phibbs and his associates when they gave ketochol, a mixture of bile acids, to dogs. There was no sign of any change from normal in the concentration of bile in the gall bladder.

But even if one could produce a greater flow of bile in and out of the gall bladder by increasing the rate of flow down the common duct, it is hard to see how this could help many patients with cholecystitis, because in this disease the infection, when demonstrable, is found not so often in the bile as deep in the muscular wall of the gall bladder. Moreover, any flushing that may be effected can hardly have any influence on stones that are too large to pass through the cystic duct. The flushing of smaller

stones into the common duct, if it could be accomplished, would probably do the patient harm rather than good. Certainly, there is no possibility of any flushing in the many cases in which the gall bladder is too badly diseased to have any function, or in which it is packed with stones or sand, or sealed off from the ducts by a stone imbedded in its neck.

Some may ask, "How about the Meltzer-Lyon type of treatment for cholecystitis?" My answer is that I never could see much logic in it and hence I have never used it. So far as I can tell, it has gone out of fashion and is seldom used today.

It would perhaps be best for the mental development of all physicians if they would oftener admit that there is no logical medical or dietary treatment for cholecystitis, especially when bile has ceased to flow easily into and out of the gall bladder, or when the organ is full of stones or its wall is stiffened with scar tissue and full of bacteria.

To those physicians who say, "But our treatment works perfectly in a high percentage of cases," the answer is that the physician who does nothing for his patients with chronic cholecystitis can point to scores of cases in which for years the man or woman has not had a pain or an ache; he, too, is getting beautiful cures. Cholecystitis being the disease that it is, with its tendency to remissions of symptoms lasting twenty years or more, no one can tell when a treatment was responsible for an apparent cure and when it was not. When, as often happens, I see old persons who have "gotten by" comfortably enough, carrying gallstones for ten or twenty or thirty years, I wonder if I should not avoid surgical treatment as often as I can, but when, as also often happens, I see someone who loses his life because a diseased gall bladder was not removed in time, I wonder if I should ever permit a person with definite cholecystitis to go without operation.

Usually, the person whose gall bladder is beginning to cause a good deal of pain and flatulence had better have it out. I recommend immediate operation also to those persons with a bad gall bladder who have to travel much or live in out-of-the-way places where a good surgeon is not available. I am not inclined to recommend operation when there are one or two stones in a functioning gall bladder and the symptoms, if any, are not those of cholecystitis.

* * *

All this is really a plea for thoughtfulness and specialization in the treatment of cholecystitis, and a protest against the unthinking treatment of all cases with the same diet and the same mixture of bile acids and a laxative.

THE SURGICAL ASPECTS OF GALLSTONES

HOWARD M. CLUTE, M.D.,* AND FRANCIS R. KENNEY, M.D.

BOSTON

AMONG lay people and many physicians as well, there is a deeply grounded belief that gallstone surgery is dangerous and is not to be advised until repeated attacks of indigestion, pain and jaundice make it absolutely inevitable. It is our belief, however, that gallstones can be safely removed if the operation is undertaken before complications have occurred. Furthermore, in the great majority of cases of simple or silent gallstones an early elective cholecystectomy is wiser than an operation into which one is forced by the complications of the disease. There is far too great a tendency to worry unduly about gallstone surgery and to forget the dangers that gallstones may produce.

Gallstone surgery is, however, decidedly major surgery, and requires far greater skill than do most surgical procedures in the abdomen. There is no question that the occasional operator can do as much or more harm in operating on the biliary tract than will result from many of the disease conditions he is treating. Strictures of the common duct, duodenal injuries and fistulas, overlooked cystic and common-duct stones — these are some of the penalties exacted by ill-advised attempts at surgery of the biliary tract. It is most important that the surgeon who elects to operate on biliary-tract disease shall be well trained and thoroughly experienced in the technic of the procedure. The dangers of gallstones lie first in the complications that they may produce and secondly in the surgery required for their removal. These dangers can to a large degree be avoided by the performance of operation before complications occur and by a better quality of surgery.

From January 1, 1935, to December 31, 1943, we operated on 356 patients with chronic cholecystitis, with or without gallstones, and its complications. This series does not include 179 patients with other types of biliary-tract disease not immediately related to gallstones who were seen during this period. In Table 1 are listed the types of biliary-tract disease encountered and the operative mortality of each.

The removal of the gall bladder for chronic cholecystitis with stones or with cholesterosis is now a completely safe procedure. In 201 cases in which operation was performed — 178 with and 23 without gallstones — there was only 1 death, a mortality rate for simple cholecystectomy of 0.5 per cent. The cause of this death was never clearly understood, since autopsy was not per-

mitted. The patient was a woman of thirty-five in good condition. The gall bladder was removed for cholesterosis and the common duct was explored; it contained no stones. Death, apparently

TABLE 1. *Types of Biliary-Tract Disease.*

TYPE OF DISEASE	No. OF CASES	DEATHS	
		NO.	PERCENTAGE

With gallstones	178	0	
Without gallstone	23	1	
Acute cholecystitis	71	5	7.0
Stones in the common duct	84	8	9.5
Totals	356	14	
General average			3.9

from shock, occurred fifteen hours after the operation. There was no evidence of hemorrhage. Thus, the only fatality in 201 patients receiving cholecystectomy for uncomplicated disease of the gall bladder was probably due to an unknown error in surgical technic or to a failure to prepare the patient more carefully for operation. The important point is that simple gallstones can be treated safely. The danger of surgery in these cases has been reduced to a minimum by the co-operative efforts of the internist, the anesthetist and the surgical team in their preoperative, operative and postoperative care.

No longer is a patient with simple gallstones seen one day and operated on the next. Time is taken to be certain that the symptoms are due to the gallstones and not to some other trouble, such as heart disease. Tests of kidney function and liver function are carried out. If anemia is present, iron therapy and transfusions are given. Extra fluids, glucose and proteins are administered to improve liver function before surgery is undertaken.

The anesthesia in surgery of the biliary tract plays a particularly important role. A gentle, short, easy operation under the complete relaxation of spinal anesthesia appears to be far safer than a long, difficult one under the incomplete relaxation of many other anesthetic agents. We realize that we are particularly fortunate in having an outstanding anesthetist associated with us, to see all cases before operation and to decide with us regarding the operative risk and the best type of anesthesia. If we could not have a trained anesthetist to give spinal anesthesia for gallbladder surgery we should use ether — or postpone the surgery. Spinal anesthesia should not be used in upper abdominal surgery unless it can be given and supervised by an experienced and well-trained anesthetist.

The postoperative use of parenteral fluids, blood transfusions and oxygen and frequent turning of the patient are of great value in keeping the surgical

*Professor of surgery, Boston University School of Medicine, surgeon-in-chief, Massachusetts Memorial Hospitals; surgeon, New England Baptist Hospital.

mortality of gallstone operations low. Each case should be followed by the surgeon himself to make certain that these measures are properly carried out. In this type of surgery routine orders cannot replace individual attention.

We and other surgeons have in the past stated that exploration of the common duct in gallstone surgery does not increase the risk and that it prolongs the hospital stay by only a few days, if at all. This viewpoint we have come to question. There is, of course, no doubt in anyone's mind that the common duct must be opened if there are positive indications for it. In a great many cases, however, there are definite indications that no stones are present in the common duct, and that it should therefore be left alone. Anything approaching a routine exploration of the common duct at the time of a simple cholecystectomy for gallstones should be avoided. Reoperation has been necessary in certain cases to remove stones left—or re-formed—in the common duct, but in every one of these the duct had been explored at the first operation. A secondary choledochostomy has not been necessary in any case in which the duct was not explored at the first operation. We now believe that choledochostomy increases the time of the surgery, opens a viscus that is easily damaged, increases the shock of the operation and the chances of postoperative complications and prolongs the hospital stay. Choledochostomy should be done only when positive indications are present. In one third of the 201 cases of simple cholecystectomy the common duct was explored, but no stones were found.

There is no intention to imply that every patient who has simple or uncomplicated gallstones should have them removed. If the patient is not a good operative risk because of old age, hypertension, heart disease or other constitutional defects, no operation for simple gallstones should be undertaken unless it appears that their removal will improve the patient's general health. As evidence of this belief, there were 81 cases not included in this study, with gallstones or probable gallstones, in which surgical removal was not advised. In all such cases consultation is sought before a final decision is reached.

The two most frequent complications of gallstones are attacks of acute cholecystitis and the passage of stones into the common duct. Seventy-one of these patients had acute cholecystitis, with a 7.0 per cent mortality, and 84 stones in the common duct, with a 9.5 per cent mortality. It is difficult to keep the statistics clear, since in some of the cases of acute cholecystitis there were stones in the common duct as well. The important point is that both the complications mentioned carry a serious mortality risk.

It has long been our contention that most cases of acute cholecystitis begin not with a bacterial infection of the biliary tract but with an obstruc-

tion of the cystic duct that interferes with the circulation of the gall bladder. Following this obstruction comes pressure on the veins, the lymphatics and even the arteries, which produces edema, infarction, necrosis and even perforation of the gall bladder. Not until this process is well established—in thirty-six to forty-eight hours—does bacterial invasion occur. Because of this basic course of the disease, immediate surgery within a day or at most two days of the onset of acute cholecystitis and before bacterial invasion occurs is wisest and safest. Delay in these cases means waiting for the onset of infection and for the possibility of perforation of the gall bladder, which occurs in about 20 per cent of the cases.

Operations on patients within twenty-four to forty-eight hours of onset are and should be safe and uncomplicated procedures. Death from acute cholecystitis has occurred in patients who have had repeated attacks of acute cholecystitis that have been "watched." Finally an attack appears that does not subside but goes on to develop infection, abscess formation, cholangitis or perforation and resulting peritonitis. All 5 patients who died from acute cholecystitis had had repeated attacks of the disease, all were between the ages of forty-five and seventy-three, with an average of sixty-one, and all were seen some days after the onset of symptoms—too late for early surgery. The causes of death were coronary infarction in 1 case, peritonitis in 2 cases and septic cholangitis in 2 cases. We are therefore convinced that the factor of delay in operating on patients with acute cholecystitis is responsible for much of the mortality, and that the proper management of these cases is surgery soon after the first attack.

One seldom sees a patient with stones in the common duct who has not had repeated attacks of gallstone colic or acute cholecystitis or both. In fact, when a surgeon operates for gallstones in a patient who has had six or eight or more attacks of colic, he must realize that it will probably be necessary to explore the common duct. Stones in the common duct are a dangerous complication of gallstones, as shown by the fact that 8 of the 84 patients with them died. Each of these patients had had repeated attacks of pain, often over a period of many years. Although 1 patient was only thirty-eight years old, all the others were over fifty-nine and the average age was sixty-three. The causes of death in this group are of some importance. In 3 cases, death followed cardiovascular accidents; in 1, post-mortem examination showed only ileus; in 2, acute generalized peritonitis was found; in 1, gas-bacillus infection had occurred; and in 1, death was apparently due to the so-called "hepatorenal syndrome."

In this group with common-duct stones, other serious disease was often found as a result of the long-standing process. Thus, jaundice was present

at least 20 per cent of the cases, fever and chills were not infrequent as evidence of cholangitis, and a fistula between the duodenum and the gall bladder was present in 3 cases.

All these facts are strong evidence that there is a far too great delay in the surgical removal of gallstones. Such complications occur only in patients who have had gall-bladder trouble for a long time. They represent the end stages of gallstone disease. The degree of permanent kidney and liver damage in the patients who survive surgery cannot be estimated, but it must be a distinct factor in later life.

This study does not include 8 cases of acute pancreatitis, although 6 of these patients had gallstones as well. In some cases there had been repeated attacks of biliary colic that were sufficiently clear to warrant a diagnosis of stones and earlier operation for them. Also excluded are 7 cases with cancer of the gall bladder or bile ducts. What relation, if any, exists between these findings and gallstones is problematic. It is, however, well known that gallstones are present in 65 per cent of patients having cancer of the gall bladder.²

We wish to emphasize the point of this paper by briefly reporting a case recently seen on the Surgical Service of the Massachusetts Memorial Hospitals.

The patient, a 73-year-old woman, had had her first attack of gallstone colic 20 years previously, and attacks had continued at varying intervals subsequently. In 1938, a diagnosis of gallstones was made by x-ray study. In 1940, the patient was operated on in this hospital for obstruction of the small bowel due to a gallstone in the ileum. In the postoperative period she developed phlebitis in each lower leg, auricular fibrillation and cardiac failure. After a stormy convalescence she was discharged. One year later attacks of gall-bladder colic reoccurred. In 1943, she was admitted to the hospital because of recurring attacks of upper abdominal pain, chills and fever. Because of a high blood pressure (230/100) and

arteriosclerotic heart disease, surgery was not undertaken. Early in 1944, the pains, fever and chills returned and were accompanied by obstructive jaundice. Operation was deemed necessary in spite of the obviously poor risk. A large fistulous opening was found between the gall bladder and the duodenum. Stones were present in both the gall bladder and the common duct. The gall bladder was removed, the stones were taken from the common duct and the duodenal opening was closed. The patient recovered and appears to be well.

How much pain and suffering could have been saved this woman by removing her gall bladder and its stones twenty years ago!

* * *

Analysis of this series indicates that gallstones, even when silent, are potentially dangerous. Simple, uncomplicated gallstones in good-risk patients can be removed with a low mortality rate. Improving the surgical technic and the preoperative and postoperative care will materially lessen the number of operative deaths. When patients have repeated attacks of gallstone colic, the chances of serious complications are great and operative mortality is high. Early operation soon after the onset of acute cholecystitis is indicated by the basic course of the disease and is warranted by the results; it will reduce the chances of stones' passing into the common duct and avoid the serious complications that follow their presence there and the resultant surgery. The removal of simple, uncomplicated gallstones is an extremely safe procedure and should be urged before the complications of gallstones appear.

RADIOLOGIC ASPECTS OF GALL-BLADDER DISEASE

MERRILL C. SOSMAN, M.D.*

BOSTON

SINCE the advent of cholecystography in 1924, the diagnosis of gall-bladder disease has become extremely simple and accurate. Its simplicity depends on the limited number of possible diagnoses. Either the x-ray reveals a gall-bladder shadow, or there is no shadow. If there is a shadow, either the gall bladder contains stones or it contains no stones. Occasionally gallstones can be demonstrated in the absence of gall-bladder visualization. In our experience at the Peter Bent Brigham Hospital only 20 per cent of all gallstones are opaque enough to be visible without cholecystography. Compared to the almost infinite number of possible diagnoses in the chest, or the gastrointestinal tract, or even in the bones, the four choices noted above are indeed simple. The variations from normal are few in number, the decision is easy, and the final opinion is frequently categorical, often indubitable.

The accuracy of the x-ray test increases with the attention paid to technical details. One must have good films to make good diagnoses. Nearly all the errors in the radiologic diagnosis of gall-bladder disease can be traced to faults in technic, assuming that the physician who interprets the films has had average experience and possesses good judgment. Under average conditions in any x-ray department doing a considerable amount of diagnostic work, the accuracy of this test approaches 99 per cent. Including borderline cases, in which it is a question of opinion whether the gall bladder is diseased enough to interfere seriously with its function, there is an absolute accuracy of at least 95 per cent. Cholecystography is almost unique in x-ray examinations in that it not only portrays the anatomy of the part under consideration and the consequences of major pathologic reactions but also shows clearly a series of physiologic processes. All other x-ray examinations except one portray anatomic structures and variations caused in them by disease or injury, but little, if any, abnormal physiology. The one exception is intravenous (excretion) urography, and this test is quite similar to cholecystography in concept and execution. The functions of the kidney, however, are so complex and the possibilities of disease, injury and tumor are so numerous that a similar accuracy in diagnosis is not to be expected.

TECHNIC OF CHOLECYSTOGRAPHY

Attention to details and a rigid, precise technic pay large dividends in diagnostic accuracy. Among the first of the important technical factors is adequate equipment — fast apparatus capable of mak-

ing good radiographs in half a second. This helps to avoid blurring of the gall-bladder image by motion, either from breathing, from peristalsis of adjacent organs or from pulsation transmitted to the gall bladder. A fast, thin Bucky diaphragm is also essential to secure good contrast. A cone centered over the gall bladder helps to increase the contrast by excluding other secondary radiations. The tube should be of fine focus to give sharp detail to the image, such as a 2-mm. focal-spot rotating-anode tube, which at the same time allows the use of 300 or 400 milliamperes of current and a correspondingly short exposure. It is most satisfactory to vary the voltage according to the thickness of the patient's abdomen as measured with him prone on the table. The intensifying screens should be clean and free of grain, and as soon as they become abraded or spotted through wear they should be replaced. There is no excuse for some of the dirty, pockmarked screens in daily use in some offices and departments. Contact between the screens and the film should be checked, since lack of close contact results in a blurred image. A target-film distance of 32 to 36 inches instead of the usual 24 to 28 inches helps to improve detail.

Next in importance to the equipment is attention to the details of the test itself. Considering only oral cholecystography at the moment, the dye (tetraiodophenolphthalein) may be administered in any one of several forms or combinations. We originally used the pure dye in enteric-coated capsules, later changing to an emulsion that was mixed with grape juice to disguise both the purple color and the metallic taste. The dye may be dispensed with a weak acid, such as citric, tartaric or malic acid, and simply mixed with water. In an acid medium the dye is precipitated as an insoluble white salt and goes through the stomach unabsorbed. In the alkaline intestinal tract the dye becomes soluble and is absorbed, passing through the portal circulation to the liver, where it is excreted along with the bile salts. It is too dilute when excreted by the liver to cast a shadow on the x-ray films, so that concentration by the gall bladder is essential in demonstrating the gall-bladder shadow. For this reason attempts to show the common duct after cholecystectomy have uniformly failed except by direct injection of opaque material — called "cholangiography" or "choledochography." The common bile duct may be widely dilated after operation and may retain a considerable amount of bile, but never in my experience has it concentrated the liver bile to a point where it could be demonstrated by radiography. A thorough understanding of the

*Clinical professor of roentgenology, Harvard Medical School; roentgenologist, Peter Bent Brigham Hospital

ve steps is essential in interpreting the results of the test.

PREPARATION OF PATIENT AND TECHNIC OF EXAMINATION

Cleansing of the intestinal tract by either catharsis or enema adds to the accuracy of the tests by removing feces, gas or undissolved dye, which may veil or obscure the gall-bladder shadow. A routine catharsis on the day preceding the examination was tried but was soon given up, since it was found that the tetraiodophenolphthalein is in itself cathartic, probably owing to the phenolphthalein portion. Many patients suffer from diarrhea and some from nausea and vomiting as well, but diarrhea has not interfered with a satisfactory visualization of the gall bladder. Obviously, however, if the patient has vomited the dye, enough may have been lost to interfere with the test. This happens particularly in patients with peptic ulcer and those with some degree of pyloric obstruction. Golden² recommends administering 6 cc. of paregoric before the meal that precedes the giving of the dye. This undoubtedly promotes the comfort of the patient and may allow more complete absorption of the chemical. We do not agree with Curl,³ who recommends a high-fat diet for several days before the test to empty the gall bladder. With this procedure there is a larger percentage of unabsorbed precipitated dye remaining in the intestines, particularly when the fat is given during the meal just preceding the administration of the dye. Theoretically this should empty the gall bladder and prepare it ideally for the storage of the bile that contains the dye. Actually it seems to interfere with the absorption of the chemical, perhaps through combination of fatty acids and tetraiodophenolphthalein to form an insoluble compound. Antonucci⁴ recommends a high-carbohydrate intake before cholecystography on the theory that a large glycogen reserve in the liver improves its excretory function. We have had no experience with this preliminary preparation.

The standard procedure, therefore, is to give 3.5 gm. of tetraiodophenolphthalein after a fat-free evening meal, the exact procedure depending on the type of preparation employed. Many hospitals are now using the double-dose technic, giving one dose of 3.0 or 3.5 gm. after a fat-free noon meal and a similar dose after a fat-free evening meal. This has definitely added to the accuracy of the test, with fewer doubtful or faint gall-bladder shadows resulting. After the evening meal and the dose of the dye, the patient should have nothing to eat or drink except water, fruit juice or black coffee until after the x-ray films are taken, usually at 9.00 the following morning. There is no evidence that limitation of fluid intake increases the concentration of the bile as it is excreted from the liver or that increased fluid intake promotes the flow of bile from the liver, so that fluids need not be withheld as in

excretion urography. It is advisable to take a large film of the right abdomen first, at least an 11-by-14-inch film, develop it immediately and view it wet, to locate the gall-bladder shadow. If there is gas or fecal material over the usual gall-bladder area, a cleansing enema — at least 2000 cc. of tap water or normal saline solution — should be used to remove it if it is in the colon, or a drink of water if there is air in the descending duodenum, which may obscure or confuse the findings. The films are best made with the patient prone, the right hand above the head, the face to the right and the right side of the abdomen raised slightly from the table. This position helps to uncover the gall-bladder shadow, particularly in long, thin patients, by rotating the spine slightly to the left and the gall bladder slightly more to the right, rendering the latter less apt to be concealed by the vertebrae. The position of the gall bladder varies tremendously. In the obese or thick-set patient of hypersthenic type it may be at the lateral edge of the liver as high as the tenth rib. In the long, lean hyposthenic patient it may lie over the sacroiliac joint or even reach the brim of the pelvis, and not infrequently it is hidden by the spine unless the position described above is used. In exceptional cases it may be necessary to take films with the patient lying face up, with the body rotated to the right to uncover the gall-bladder shadow either from the spine or from gas in the hepatic flexure. Films in the upright position are occasionally of critical value, as will be shown later. If repeated cleansing enemas are not successful in removing troublesome gas from the gall-bladder area, either the supine technic should be tried or 1 cc. of Pitressin should be given hypodermically, provided there is no contraindication to its use. A satisfactory scout film should include the lower half of the liver shadow and the upper half of the innominate bone, as well as the lumbar spine. In viewing the wet film one should identify the liver edge, the kidney shadow, the iliopsoas shadow and the peritoneal line laterally. Occasionally the overlapping of liver and kidney shadows produces a zone of increased density, which to the uninitiated seems to be the gall-bladder shadow. In 2 routine cases the air-filled fundus of the stomach was recognized in the area where the liver shadow should have been, indicating a situs transversus. In both cases, films of the left upper quadrant demonstrated a normal gall-bladder shadow and averted a serious error in diagnosis. If the shadow is visualized satisfactorily, at least three films are taken, with a cone centered over the area where the gall bladder lies. It has been found advantageous to take these films with slight variation in rotation, and one of them at least at the end of expiration. This often helps one to decide whether overlying shadows, either so-called "positive" or "negative," maintain a constant relation to the gall-bladder shadow, thus aiding in differentiating bubbles of air or

gas and calculi. If these films are technically satisfactory, the patient is given a fat meal, — two eggs, buttered toast and coffee with cream or an eggnog containing two eggs and some cream, — and at least two more films are taken an hour later, using the same position and technic as for the first set of films. If the first films show questionable shadows that may be those of calculi, two films should be taken in the upright position to demonstrate a change in the position of the calculi. Elias, ⁵ in 1932, was the first to show that some gallstones float in the opaque dye-filled bile, whereas most of the calculi sink to the fundus of the gall bladder when the films are made with the patient erect. This was confirmed and amplified by Akerlund. ⁶ The floating phenomenon is an extremely interesting and useful test, frequently changing the final diagnosis from a doubtful to an indubitable one. The stones that float at a given level in the upright position are always the cholesterol or "negative" calculi, and the phenomenon is based on the fact that there is a difference between the specific gravity of the bile in the fundus of the gall bladder, which has been there longest and is therefore the most concentrated, and that of the bile in the neck of the gall bladder, which has come more recently from the liver and is less concentrated and therefore of lower specific gravity. The cholesterol calculi simply seek their own level of specific gravity, and they usually lie in a single horizontal plane, causing a dark streak across the opaque white gall-bladder shadow. ⁷ Frequently the separate calculi are recognizable. It is conceivable that if there were two different kinds of calculi, there would be two separate and distinct horizontal rows in the upright position, but I do not remember having seen this actually demonstrated by x-ray. Nearly all the calculi we see are of the same type or kind in a given gall bladder, and most of the cholesterol calculi were probably laid down in a single shower. Many of them also are seen in gall bladders that concentrate and empty well, so that they must have been made through a physicochemical process at a time when the gall bladder was normal or nearly normal, at least in function. The opaque crystalline pigment calculi also frequently occur in normal gall bladders, but the laminated calculi and those with dense margins around a cholesterol nucleus are oftener found in badly diseased gall bladders, and recurrent infection has probably played a part in their formation. Only the small negative or pure cholesterol calculi float, and the bile must be well concentrated and quite opaque to present this phenomenon. By far the larger majority of calculi, including all the "positive" ones, sink to the fundus of the gall bladder in the upright films, forming a layer of debris at that point. This is just as valuable, however, in identifying them as biliary calculi as is the floating phenomenon across the middle of the opaque gall-bladder shadow.

The films taken an hour after a meal or after the eggnog should also be developed at once and viewed wet before the patient leaves the department. If there has not been at least a 50 per cent decrease in the size of the shadow, further films should be made an hour or two later. The significance of a persistent gall-bladder shadow that does not decrease in size after a meal is discussed below. A proprietary mixture of concentrated lipoids, such as Cholex (National Synthetics Company), is available, and this may be used in place of a fat-containing meal. Its chief advantage is its small bulk and its ease of preparation. It is particularly useful for patients who do not like eggs and for those who are nauseated by the thought of food.

The entire examination as a rule takes only slightly over an hour and requires only two sets of films, as described above — one set fifteen hours after taking the dye and the other at least an hour after the test meal. We originally made several sets of films during the day, ⁸ the patient fasting in the meantime, to demonstrate progressive increase in the density of the shadow as an index of normal concentrating power. After twenty years of experience, we know the expected standard of density at the fifteen-hour examination, and believe that it is unnecessary to prolong the examination beyond the two sets of films, except in case no gall-bladder shadow is demonstrable at the first examination. It has been our custom to check each case of nonvisualization by intravenous injection at a subsequent date. Most roentgenologists, however, prefer to repeat the oral method, and if this is done it is advantageous to do it the following day, the patient being on a fat-free diet the entire time. This obviates hospitalization, which should be done for intravenous injection, and avoids the risks of reaction from the injection, both local and systemic. If any of the dye gets into the tissues around the vein being injected, an intense local reaction is set up. Some patients have had thrombosis of the vein after injection, a few have had acute coronary attacks, and several sudden deaths have been reported after intravenous injection of tetraiodophenolphthalein. Systemic reactions are less apt to occur if the dye is injected slowly — over a period of at least fifteen minutes. Because of these possible reactions many x-ray departments have abandoned the intravenous method entirely and rely on the oral method, using the double dose either routinely or as a check on the single dose if nonvisualization of the gall bladder occurs. In either case a small percentage of patients show a normal gall-bladder shadow at the second examination, when none was seen the first time. This varies from 2 to 10 per cent in different clinics. Many of these shadows are probably the result of errors in technic, either by the patient, who perhaps misunderstood the directions or willfully disregarded them, or by the radiographer, who did not pay attention to the details.

ed above. A careful, conscientious, well-trained technician is an invaluable asset, particularly in this field.

There is a third possibility to be considered — that the gall bladder is visualized but with a shadow darker than normally expected at the given time. In such cases it is wise to repeat the examination, using either the intravenous method — if there is no suspicion of coronary disease — or the double-exposure method. Tracey⁹ strongly advises checking the collateral organic systems — by a gastrointestinal series, a barium enema and so forth — and delaying symptomatic treatment for a short period before rechecking the gall bladder, intimating that there may be physiologic variations that interfere with the test. He states that if the symptoms are relieved by treatment there may be good visualization of a previously faint or nonvisualized gall bladder. Lahey and Jordan¹⁰ go so far as to state that of patients with chronic dyspepsia and nonvisualization of the gall bladder 44 per cent show normal gall-bladder shadows after satisfactory bowel management. Our series has shown no such discrepancy. This is certainly true, however, in the case of jaundice. No harm has followed if the dye is given either intravenously or orally in jaundiced patients, but almost invariably there is nonvisualization of the gall bladder. A good shadow is occasionally obtained when the jaundice is clearing or it is due to hemolysis and not to obstruction. It is much better, however, to wait until the jaundice has entirely cleared before doing a cholecystography. There is no danger in trying it, but it constitutes a waste of time, material and money.

It is of course obvious that if pyloric obstruction or prolonged pylorospasm is present, the dye may be retained in the stomach unabsorbed, in which case nonvisualization obviously results. This complication can be recognized by identifying the finely mottled opaque shadow of the dye in the stomach. In a recent case of this type further gall-bladder films twenty-four hours later revealed passage of all the dye from the stomach and a normal gall-bladder shadow, whereas there was no shadow before. Such a complication may explain the discrepancies noted above between the results reported by Lahey and Jordan and our figures.

Fluoroscopy has not been used routinely in our department since the first days when we were repeating Graham and Cole's experiments,¹¹ and only a few roentgenologists now use fluoroscopy as part of cholecystography. We found it to be of no help in the clinical examination, and now use it only in an occasional patient when spot films in the upright position are desired. Good films give much more information, especially concerning detail, than can be expected from fluoroscopy. The information obtained by fluoroscopy about changes in shape and in position with palpation and change in posture is

not of enough importance to justify the time consumed by the method.

Recently a new drug has been found that also renders the gall bladder opaque some hours after ingestion. This substance is in no way related to tetraiodophenolphthalein, and it is less apt to cause some of the uncomfortable side effects such as nausea, vomiting and diarrhea. Originally described in Germany as "Biliselectan,"¹² it is *beta*-(4-hydroxy-3,5-diiodophenyl)-*alpha*-phenyl-propionic acid. It is dispensed as a 0.5-gm. tablet, and is taken by mouth with sips of water, lemonade or weak tea after a fat-free evening meal, just as in the oral method with tetraiodophenolphthalein. So far, after use in about 150 patients, it has shown several distinct advantages over tetraiodophenolphthalein. There is definitely less toxic reaction, such as nausea, vomiting and diarrhea, in the gastrointestinal tract, and there is usually little if any opaque residue in the bowel to obscure the gall-bladder area. The drug is excreted largely through the kidneys, and a few patients complain of mild burning on urination the morning after taking the tablets. In this country it is manufactured by the Schering Corporation under the trade name of Priodax and by the National Synthetics Company as Dikol. We have been using it routinely since preliminary clinical tests demonstrated its advantages. The standard dose is 3.0 gm. (six tablets). Double doses have frequently been given without untoward results and with excellent visualization of the gall bladder at fifteen hours, with as dense a shadow as any seen following intravenous administration of tetraiodophenolphthalein. In fact, the shadow is often so opaque that small stones may be entirely hidden. This chemical has not been accepted for intravenous injection. It will probably replace the various forms of tetraiodophenolphthalein preparations in most x-ray departments for oral use.

INTERPRETATION OF RESULTS

The facts that may be demonstrated by cholecystography are the size, shape and position of the gall bladder, the degree of filling and the relative concentration, the presence or absence of shadows indicative of calculi and the amount of emptying, as revealed by a decrease in size, usually one hour after a fat-containing meal.

The size, shape and position of the gall bladder are extremely variable. A small gall bladder, if of normal density, does not indicate inability to fill normally; rather it suggests that the patient has partaken of forbidden food. A large gall bladder is of no clinical importance unless there is lack of concentrating power or other evidence of disease. A markedly distended gall bladder, if due to obstruction anywhere in the biliary tract, either fails to fill with the dye or does not concentrate it. A gall-bladder shadow of normal density for the given

method should therefore be considered normal regardless of its size, if the other findings are also normal. The position of the gall bladder depends on the habitus of the patient, as noted above. Changes in position alone are of no value in interpretation, unless the cause of displacement can be demonstrated. Situs inversus should always be kept in mind because of the possible error in interpretation as a case of nonvisualization. Changes in shape, however, are occasionally important, usually as an indication of fixation or adhesions by extrinsic disease. In actual practice this is rare unless there is a history of surgical drainage of the gall bladder. Most of the dense adhesions found at operation cannot be demonstrated or even suspected by x-ray examination. It must be remembered that one is viewing a three-dimensional object in only two dimensions and that any abnormal or peculiar shape must be interpreted accordingly. The fundus of the gall bladder is frequently seen partly overlapping the body of the shadow. This is as a rule not due to adhesions but to the free portion's folding over the portion that is normally fixed to the undersurface of the liver. Rarely the gall bladder is more or less divided into two or three compartments by either transverse or oblique bands. These may be either partial septums in the wall of the gall bladder — usually in the mucosal layer — or bands compressing it extrinsically. In either case, the finding is of little or no importance per se. Such gall bladders usually fill, concentrate and empty to a normal degree, and the few patients in this series that have been operated on without other indications have not had their symptoms relieved by cholecystectomy.

The filling of the gall bladder with dye-laden bile obviously depends on its ability to empty. If it cannot empty, there is poor filling and a faint shadow or no filling with fresh bile and no shadow. In either case the interpretation is based on the density of the shadow and is inseparable as a fact from the observations based on lack of concentration. If there is no visualization of the gall bladder by opaque material, the logical and correct interpretation is a nonfunctioning gall bladder.*

If the radiographic technic has been above criticism and the patient has faithfully followed directions, this is a very reliable finding. In 90 per cent of nonvisualized gall bladders in our series gallstones have been found at operation. The accuracy of this finding alone is close to 99 per cent, in terms of grossly pathologic gall bladders, particularly if the examination has been repeated either by intravenous injection or by the double-dose technic and the find-

ing has been verified. Much less reliable, however, has been the demonstration of a poorly functioning gall bladder or a faint shadow, particularly by the single-dose oral method. Gross pathologic changes were found at operation in only 75 per cent of those in this group who came to operation. A cholecystographic examination giving this finding without calculi should of course be repeated, preferably by intravenous injection, so that all question of failure of absorption of the dye can be eliminated. So far we have found fewer errors in this group with Pridax, particularly with the double-dose technic. If the symptoms are not characteristic or acute, it may be wise to delay the second examination for several weeks, as Tracey⁹ suggests. On the whole, if a shadow of fair to good density results, no calculi are found and the gall bladder empties promptly and well, it is safer to class the result as within the normal range rather than to try to estimate the shadows of fair density in terms of moderate degrees of cholecystitis.

It should be noted that our results are not based on histologic examination of the excised gall bladder alone. Autopsies have shown that 60 per cent of people over forty years of age have noncalculous cholecystitis, but mostly of mild degree and of doubtful significance as regards the production of distressing symptoms.¹³ Most if not all of this mild cholecystitis would be classed by us as no more than normally expected, and if no gall-bladder shadow were obtained in such a patient we should consider it an error rather than a success.

The radiographic demonstration of calculi, however, is the most reliable finding of all, and the most significant to the patient, the physician and the surgeon. In our series this finding in patients coming to operation has been accurate in over 99 per cent and there have been several years when it has been 100 per cent correct. Many patients in whom gallstones have been reported do not have the finding either verified or disproved, and this leaves a possible source of error, since they are apt to be the ones with milder symptoms. If the x-ray films are of excellent quality and if calculi, either positive or negative, are demonstrated, there should be no more than a 1 per cent chance of error. The causes of these errors are discussed below. It must be emphasized, however, that not all gallstones can be visualized, since there are many cases of calculous cholecystitis in the cases with nonvisualized gall bladders in which the calculi are not radiopaque. Of all the cases coming to operation in which gallstones were found, calculi were positively reported in only 75 per cent. The others not identified preoperatively, however, were reported as nonfunctioning or pathologic gall bladders, and as noted above we have learned that 9 out of 10 patients in this group are found at operation or autopsy to have biliary calculi. The routine films taken one hour after the meal have been helpful in securing this

*The results of cholecystographic examination should not be reported as "positive" or "negative." To one person the report "The Graham test was negative" means that a normal gall bladder was found. To another it may mean that the results were negative; that is, that no gall-bladder shadow was seen. It is better to choose words that allow of no misunderstanding or misinterpretation — for example, "nonvisualization of (nonfunctioning) gall bladder," "cholelithiasis" and "poor concentration."

a degree of accuracy, since the decrease in the of the gall-bladder shadow has several times covered small calculi hidden in the opaque bile. Right films in doubtful cases have added to the accuracy. The interval of time between the two of films and sometimes the slight shift in position of the gall-bladder shadow owing to food in the stomach and duodenum have also occasionally helped to decide that a questionable shadow was beside the gall bladder and not a biliary calculus. The demonstration of biliary calculi radiographically should not be accepted as the chief indication for surgical intervention. It should, however, be accepted as an extremely trustworthy finding on which a decision to operate may be based. In my experience the patients with calculous cholecystitis and biliary symptoms have experienced a high degree of relief following cholecystectomy, whereas those without calculi have frequently shown no clinical improvement after removal of the gall bladder. The percentage of cholecystectomies for calculous cholecystitis could be used as a check on the conservatism and judgment of the surgeon. In this hospital and in the series of 1032 consecutive cholecystectomies reported by Wilkinson,¹⁴ 90 per cent showed gallstones.

It must be emphasized that x-ray examination of the gall bladder, or of any organ of the body, does not explain symptoms. Gallstones may be silent for long periods of time. The demonstration of calculi in the gall bladder is a factual finding, but their relation to the patient's symptoms is quite another problem, and if there is a discrepancy the referring physician should have the other organs or systems investigated.

The emptying of the gall bladder in response to the specific demand from certain foods is of doubtful value in diagnosis. Certainly if the gall bladder does contract normally, — at least a 50 per cent decrease in volume in one hour, — this response can be considered as an added index of normality. Not infrequently, as noted above, the changes in size, shape and position are helpful in other ways. In many cases the contraction of the gall bladder forces the more opaque bile into the cystic and common ducts so that they can be clearly outlined and studied. The tortuous course of the dye in the neck of the gall bladder through the valves of Heister should be recognized, and not misinterpreted as calculi or polyps. Not infrequently a calculus in the cystic duct can be located in this way. If, however, the gall bladder fails to respond to the fat meal and does not decrease in size, little or no importance can be attributed to this finding. In the great majority of patients the delay in emptying is physiologic and of no clinical importance. Obviously if the patient has pylorospasm and the fat meal does not get into the small intestine, there will be no absorption and no contraction of the gall bladder. I have seen this sequence of events from nausea,

headache, pain, emotion and many other causes. When we¹ were experimenting with various foods in an attempt to determine their relative effect on the emptying time of the gall bladder, we noted that a cupful of olive oil gave an immediate and marked response in an Italian patient, who considered it a tasty drink. A similar dose, however, had no effect on the gall bladder of the next patient, one of Scottish-Irish extraction, in whom nausea and probably pylorospasm were the only results. Inasmuch as normal pancreatic secretion is essential to the digestion and absorption of fats, we at first thought that failure of emptying of the gall bladder might be due to pancreatic deficiency. This may be an occasional cause, but this is not a reliable method of indicating it. Rigler¹⁵ states that failure to empty indicates poor function of the gall bladder or valvular obstruction of its neck, and Golden² says that lack of contraction may be due to a thick-walled gall bladder or to debilitating conditions, and in 1 case was due to tuberculous peritonitis. In my experience, however, it is better to discard this finding as an index of gall-bladder disease unless there is irregularity of outline or rigidity of the walls, which would support the finding and at the same time explain it by pericholecystic disease or tumor.

ERRORS IN INTERPRETATION

Holmes¹⁶ rightly states that variations in the density of the gall-bladder shadow are due to faulty technic oftener than to disease. This assertion might well be expanded by saying that errors in interpretation of all sorts, including faintness of the shadow, are due to errors in technic oftener than to failure of the test itself.

Some of the possible errors have already been pointed out. Another source of error is in reality due to a failure of the test, since it has been shown that a moderate degree of chronic cholecystitis or even an acute cholecystitis is compatible with normal function and a normal cholecystographic shadow. Cholesterosis, or so-called "strawberry gall bladder," may be present and not interfere with gall-bladder function as demonstrated by this test. Several times, however, we have noted a fine irregularity in outline of a normally opaque shadow, due to diffuse cholesterosis of the mucosa of the gall bladder but not interfering with its function. Gas, either in the colon or in the descending duodenum, has been the greatest cause of error. Either the stones were hidden or obscured by overlying gas or a persistent bubble of gas was interpreted as a calculus. Motion due to breathing during the exposure is another frequent source of error, since it may blur out the shadows of calculi. This is a particularly important factor in large charity hospitals and teaching clinics, in which many patients do not speak or understand the English language. It is a constant source of wonder that many people do not know how to hold their breath even for one

method should therefore be considered normal regardless of its size, if the other findings are also normal. The position of the gall bladder depends on the habitus of the patient, as noted above. Changes in position alone are of no value in interpretation, unless the cause of displacement can be demonstrated. Situs inversus should always be kept in mind because of the possible error in interpretation as a case of nonvisualization. Changes in shape, however, are occasionally important, usually as an indication of fixation or adhesions by extrinsic disease. In actual practice this is rare unless there is a history of surgical drainage of the gall bladder. Most of the dense adhesions found at operation cannot be demonstrated or even suspected by x-ray examination. It must be remembered that one is viewing a three-dimensional object in only two dimensions and that any abnormal or peculiar shape must be interpreted accordingly. The fundus of the gall bladder is frequently seen partly overlapping the body of the shadow. This is as a rule not due to adhesions but to the free portion's folding over the portion that is normally fixed to the undersurface of the liver. Rarely the gall bladder is more or less divided into two or three compartments by either transverse or oblique bands. These may be either partial septums in the wall of the gall bladder — usually in the mucosal layer — or bands compressing it extrinsically. In either case, the finding is of little or no importance per se. Such gall bladders usually fill, concentrate and empty to a normal degree, and the few patients in this series that have been operated on without other indications have not had their symptoms relieved by cholecystectomy.

The filling of the gall bladder with dye-laden bile obviously depends on its ability to empty. If it cannot empty, there is poor filling and a faint shadow or no filling with fresh bile and no shadow. In either case the interpretation is based on the density of the shadow and is inseparable as a fact from the observations based on lack of concentration. If there is no visualization of the gall bladder by opaque material, the logical and correct interpretation is a nonfunctioning gall bladder.*

If the radiographic technic has been above criticism and the patient has faithfully followed directions, this is a very reliable finding. In 90 per cent of nonvisualized gall bladders in our series gallstones have been found at operation. The accuracy of this finding alone is close to 99 per cent, in terms of grossly pathologic gall bladders, particularly if the examination has been repeated either by intravenous injection or by the double-dose technic and the find-

ing has been verified. Much less reliable, however, has been the demonstration of a poorly functioning gall bladder or a faint shadow, particularly by the single-dose oral method. Gross pathologic changes were found at operation in only 75 per cent of those in this group who came to operation. A cholecystographic examination giving this finding without calculi should of course be repeated, preferably by intravenous injection, so that all question of failure of absorption of the dye can be eliminated. So far we have found fewer errors in this group with Pridax, particularly with the double-dose technic. If the symptoms are not characteristic or acute, it may be wise to delay the second examination for several weeks, as Tracey⁹ suggests. On the whole if a shadow of fair to good density results, no calculi are found and the gall bladder empties promptly and well, it is safer to class the result as within the normal range rather than to try to estimate the shadows of fair density in terms of moderate degrees of cholecystitis.

It should be noted that our results are not based on histologic examination of the excised gall bladder alone. Autopsies have shown that 60 per cent of people over forty years of age have noncalculous cholecystitis, but mostly of mild degree and of doubtful significance as regards the production of distressing symptoms.¹³ Most if not all of this mild cholecystitis would be classed by us as no more than normally expected, and if no gall-bladder shadow were obtained in such a patient we should consider it an error rather than a success.

The radiographic demonstration of calculi, however, is the most reliable finding of all, and the most significant to the patient, the physician and the surgeon. In our series this finding in patients coming to operation has been accurate in over 99 per cent and there have been several years when it has been 100 per cent correct. Many patients in whom gallstones have been reported do not have the finding either verified or disproved, and this leaves a possible source of error, since they are apt to be the ones with milder symptoms. If the x-ray films are of excellent quality and if calculi, either positive or negative, are demonstrated, there should be no more than a 1 per cent chance of error. The causes of these errors are discussed below. It must be emphasized, however, that not all gallstones can be visualized, since there are many cases of calculous cholecystitis in the cases with nonvisualized gall bladders in which the calculi are not radiopaque. Of all the cases coming to operation in which gallstones were found, calculi were positively reported in only 75 per cent. The others not identified preoperatively, however, were reported as nonfunctioning or pathologic gall bladders, and as noted above we have learned that 9 out of 10 patients in this group are found at operation or autopsy to have biliary calculi. The routine films taken one hour after the meal have been helpful in securing this

*The results of cholecystographic examination should not be reported as "positive" or "negative." To one person the report "The Graham test was negative" means that a normal gall bladder was found. To another it may mean that the results were negative; that is, that no gall-bladder shadow was seen. It is better to choose words that allow of no misunderstanding or misinterpretation — for example, "nonvisualization of (nonfunctioning) gall bladder," "cholelithiasis" and "poor concentration."

high degree of accuracy, since the decrease in the size of the gall-bladder shadow has several times uncovered small calculi hidden in the opaque bile. Upright films in doubtful cases have added to the accuracy. The interval of time between the two sets of films and sometimes the slight shift in position of the gall-bladder shadow owing to food in the stomach and duodenum have also occasionally helped to decide that a questionable shadow was outside the gall bladder and not a biliary calculus.

The demonstration of biliary calculi radiographically should not be accepted as the chief indication for surgical intervention. It should, however, be accepted as an extremely trustworthy finding on which a decision to operate may be based. In my experience the patients with calculous cholecystitis and biliary symptoms have experienced a high degree of relief following cholecystectomy, whereas those without calculi have frequently shown no clinical improvement after removal of the gall bladder. The percentage of cholecystectomies for noncalculous cholecystitis could be used as a check on the conservatism and judgment of the surgeon. In this hospital and in the series of 1032 consecutive cholecystectomies reported by Wilkinson,¹⁴ 90 per cent showed gallstones.

It must be emphasized that x-ray examination of the gall bladder, or of any organ of the body, does not explain symptoms. Gallstones may be silent for long periods of time. The demonstration of calculi in the gall bladder is a factual finding, but their relation to the patient's symptoms is quite another problem, and if there is a discrepancy the referring physician should have the other organs or systems investigated.

The emptying of the gall bladder in response to the specific demand from certain foods is of doubtful value in diagnosis. Certainly if the gall bladder does contract normally, — at least a 50 per cent decrease in volume in one hour, — this response can be considered as an added index of normality. Not infrequently, as noted above, the changes in size, shape and position are helpful in other ways. In many cases the contraction of the gall bladder forces the more opaque bile into the cystic and common ducts so that they can be clearly outlined and studied. The tortuous course of the dye in the neck of the gall bladder through the valves of Heister should be recognized, and not misinterpreted as calculi or polyps. Not infrequently a calculus in the cystic duct can be located in this way. If, however, the gall bladder fails to respond to the fat meal and does not decrease in size, little or no importance can be attributed to this finding. In the great majority of patients the delay in emptying is physiologic and of no clinical importance. Obviously if the patient has pylorospasm and the fat meal does not get into the small intestine, there will be no absorption and no contraction of the gall bladder. I have seen this sequence of events from nausea,

headache, pain, emotion and many other causes. When we¹ were experimenting with various foods in an attempt to determine their relative effect on the emptying time of the gall bladder, we noted that a cupful of olive oil gave an immediate and marked response in an Italian patient, who considered it a tasty drink. A similar dose, however, had no effect on the gall bladder of the next patient, one of Scottish-Irish extraction, in whom nausea and probably pylorospasm were the only results. Inasmuch as normal pancreatic secretion is essential to the digestion and absorption of fats, we at first thought that failure of emptying of the gall bladder might be due to pancreatic deficiency. This may be an occasional cause, but this is not a reliable method of indicating it. Rigler¹⁵ states that failure to empty indicates poor function of the gall bladder or valvular obstruction of its neck, and Golden² says that lack of contraction may be due to a thick-walled gall bladder or to debilitating conditions, and in 1 case was due to tuberculous peritonitis. In my experience, however, it is better to discard this finding as an index of gall-bladder disease unless there is irregularity of outline or rigidity of the walls, which would support the finding and at the same time explain it by pericholecystic disease or tumor.

ERRORS IN INTERPRETATION

Holmes¹⁶ rightly states that variations in the density of the gall-bladder shadow are due to faulty technic oftener than to disease. This assertion might well be expanded by saying that errors in interpretation of all sorts, including faintness of the shadow, are due to errors in technic oftener than to failure of the test itself.

Some of the possible errors have already been pointed out. Another source of error is in reality due to a failure of the test, since it has been shown that a moderate degree of chronic cholecystitis or even an acute cholecystitis is compatible with normal function and a normal cholecystographic shadow. Cholesterosis, or so-called "strawberry gall bladder," may be present and not interfere with gall-bladder function as demonstrated by this test. Several times, however, we have noted a fine irregularity in outline of a normally opaque shadow, due to diffuse cholesterosis of the mucosa of the gall bladder but not interfering with its function. Gas, either in the colon or in the descending duodenum, has been the greatest cause of error. Either the stones were hidden or obscured by overlying gas or a persistent bubble of gas was interpreted as a calculus. Motion due to breathing during the exposure is another frequent source of error, since it may blur out the shadows of calculi. This is a particularly important factor in large charity hospitals and teaching clinics, in which many patients do not speak or understand the English language. It is a constant source of wonder that many people do not know how to hold their breath even for one

second. This is an additional reason for having the films made with as short an exposure as possible. An occasional kidney stone may simulate a gallstone, but oblique or lateral films practically always separate the two organs. An occasional explanation of error lies in the fact that patients sometimes pass their stones, either through the cystic and common ducts or by direct ulceration into the duodenum. Small calculi may be hidden by the opaque bile, but they should be seen in films of the partly emptied gall bladder or in upright films. Occasionally a gall bladder full of milk-of-calcium bile may simulate a normal cholecystogram. This error can be avoided by taking films before the dye is given or by repeating the films a week later without the dye. Usually such a shadow has a granular appearance, which is easily recognizable if the films are of excellent quality. Nonvisualization may be the result of lack of absorption of the dye from the intestinal tract or in rare cases to liver disease, either tumor or metastases, cirrhosis or chronic passive congestion. In a very few cases there is congenital absence of the gall bladder.

Overlapping shadows may be erroneously interpreted as calculi; thus, a small calcified hydatid cyst or even a Ghon tubercle deep in the posterior costophrenic sinus, which, in an obese or broad-chested patient, may actually overlie the gall bladder when the films are made in deep inspiration, may cause confusion. If one film is taken at the end of expiration this mistake can be avoided. Anomalies of the gall bladder are rare. An occasional diverticulum of the gall bladder is found, but oftener the supposed diverticulum is due to a septum in the wall of the gall bladder. Papillomas or adenomas of the gall bladder may simulate calculi. They are usually single, are rarely over 0.5 cm. in diameter and are marginal in location, according to Kirklin.¹⁷ They can be seen only or best on the films made after partial emptying. Upright films are most important in their accurate identification, since these shadows do not change position as would stones. Papillomas, polyps and adenomas are of course recognizable only in dye-filled gall bladders. Their possible relation to cancer of the gall bladder is highly questionable. Theoretically it is possible to diagnose an early carcinoma of the gall bladder by cholecystography, but so far I do not know of its having been done. It is probably wise to remove the gall bladder, however, when papillomas are demonstrated, just as it is wise to urge cholecystectomy when biliary calculi are revealed.¹⁸

The presence of cholecystitis in either an acute or a mild chronic stage and with a normal gall-bladder shadow has already been mentioned as an error in diagnosis. The clinical importance of a so-called "mild chronic cholecystitis" is doubtful. If these cases are excluded, there will be a high accuracy in the confirmed diagnosis of normal gall bladder, although it is hardly fair to accept the

diagnosis as confirmed if the gall bladder is removed. Small gallstones may be missed by palpation alone during operation.

Occasionally small stones or gritty particles like sand are found in the gall bladder at operation when the shadow appeared quite normal. This was quite rare in our experience. Others have reported the finding in 5 per cent of cholecystographically normal gall bladders. The more attention is paid to technical details, the smaller this percentage will be, particularly if upright films are taken routinely, as is now being done in some clinics.

Before cholecystography was announced by Graham and Cole,¹¹ much emphasis was placed on the so-called "indirect signs" of gall-bladder disease. A presumptive diagnosis of gall-bladder disease was often made, based on slight deformities of the duodenal bulb, pressure effects on the duodenum, irritability of the duodenal cap and pylorospasm, any of these signs alone. As now known, these alleged diagnoses were mostly guesswork, and little if any attention is now paid to these minor physiologic or anatomic changes when considering gall-bladder disease. Only rarely does the diseased gall bladder cause deformity of the duodenal cap, and the diagnosis of adhesions from the gall bladder extremely infrequent. Occasionally, however, it can be made accurately and logically, particularly when there is a fistula between the duodenum and the biliary tract. This occurs oftenest as the result of ulceration of a stone or stones from the gall bladder into the duodenum, less often by perforation of a duodenal ulcer into the common bile duct and even less frequently as the result of a carcinoma of the papilla with incompetence of the sphincter of Oddi. The rupture of gallstones into the duodenum occurs most frequently in old women, and if the stone is large enough, it may cause obstruction of the small bowel, usually near the ileocecal valve. Gallstone ileus can be promptly diagnosed by demonstrating the calculus in the obstructed small bowel, by noting air or gas in the gall bladder or biliary tract or by demonstrating the fistulous connection with barium. Films of the abdomen taken for intestinal obstruction or acute abdominal symptoms should always include at least the lower half of the liver, and the roentgenologist should always look for air in the common or hepatic ducts. One sees only what one looks for, and it is wise to train oneself to look for streaks of air in the liver shadow. The disappearance of calculi, particularly large calculi, previously known to have been in the gall bladder is presumptive evidence of perforation or rupture of the gall bladder. Smaller calculi may be passed into the duodenum through the intact cystic and common ducts. This may account for an occasional error in diagnosis when gallstones demonstrated by x-ray are not found at operation, particularly if the operation is done some time after the x-ray examination. The passage of calculi from the

gall bladder directly into the duodenum is probably more frequent than statistics indicate, since we usually see several cases a year. Frequently the stones are passed uneventfully in the stools. Occasionally they are vomited — a dramatic method of demonstrating gallstones. The fistulas may heal spontaneously, whereas with others there is a prolonged period of intermittent chills and fever, frequently without jaundice. Rarely if ever can a normal gall-bladder shadow be found by cholecystography after such a spontaneous perforation, but cases have been reported in which subsequent crops of gallstones have formed.

There is one condition in which an erroneous diagnosis of gallstone ileus is sometimes made. There may be concretions or calculi in the appendix that exactly simulate gallstones — laminated, faceted ring shadows that are in reality appendicoliths. If there is an associated ileus from acute appendicitis or peritonitis, the calculi may be interpreted as being in the terminal ileum and as causing obstruction of the small bowel. There is no air in the biliary system, however, in such a case, and that should put one on his guard.

Fistulas from the gall bladder may also lead to the stomach, to the colon, to other parts of the small bowel and even through the diaphragm into a bronchus. In any case with biliary fistula the gall bladder cannot be visualized by cholecystography, but on rare occasions it can be visualized by a barium meal or by a barium enema.

The direct demonstration of opaque or positive gallstones by x-ray films without cholecystography is quite reliable and rarely needs to be confirmed by the Graham test. Occasionally renal calculi simulate the typical ring shadows or faceted appearance of gallstones, particularly if they are formed in a hydronephrotic, pyonephrotic or polycystic kidney. Oblique films, lateral films or those made in different phases of respiration usually suffice to differentiate them. Occasionally it is necessary to do both cholecystograms and pyelograms to be sure where the calculi are located. Calcified lymph nodes are occasionally mistaken for gallstones, but fortunately they are rare in the gall-bladder area. Biliary-pigment calculi may look very much like calcified nodes, so that the reverse error is also possible, and has been made. When the cystic duct is completely obstructed, the gall-bladder mucosa may excrete calcium into the bile¹⁹ and form milk-of-calcium bile, which may exactly simulate a normally dense gall-bladder shadow. It may form a calcified cast of the gall bladder, or the calcium may be deposited in the wall of the gall bladder. These complications can be recognized by plain films of the gall-bladder area before cholecystography.

Cholangiography is a valuable method of examination when stones in the common bile duct are suspected. If it is done during operation, using a portable x-ray apparatus, it is classed as "immedi-

ate";²⁰ if it is done several days or more after operation, it is spoken of as "delayed."²¹ The latter is much to be preferred, since it can be done under fluoroscopic observation and control, with spot films as indicated. The size, shape, location and direction of the common duct and hepatic duct can be demonstrated, obstructions located, patency determined and emptying into the duodenum observed. We prefer to use lipiodol or Iodochloral, but Thorotrast or Diodrast can be successfully employed. The opaque material is injected slowly through the drainage tube or T tube, using very gentle pressure, and its progress is carefully watched on the fluoroscopic screen. If an obstruction or a filling defect is encountered, spot films are made at once, since small calculi or debris may be covered up by too much opaque material. It is not always possible to differentiate calculi in the common duct and bubbles of air or small blood clots. In the latter case re-examination several days later may give perfectly normal results. Not infrequently one or more of the pancreatic ducts are visualized if they empty into the common duct. Cholangiography is probably of the greatest usefulness when there is a question whether it is safe to remove the drainage tube. It is invaluable and essential when such operations as reconstruction of the common bile duct have to be done.

SUMMARY

Cholecystography is a simple, safe and extremely accurate method for the study of the gall bladder.

Good films are necessary if good diagnoses are to be made. Films of exceptional quality give the greatest accuracy. The utmost attention to technical detail pays dividends in diagnostic correctness.

The positive diagnosis of gallstones or of a non-functioning gall bladder should be correct in 99 per cent of the cases.

A new chemical (Priodax), not related to tetraiodophenolphthalein, has been tried successfully and is thought to be superior in routine oral examinations of the gall bladder to chemicals previously used.

The details of radiographic technic and the principles of roentgenologic interpretation are discussed.

ENDOCRINE ASPECTS OF CANCER (Concluded)*

IRA T. NATHANSON, M.D.†

BOSTON

CLINICAL OBSERVATIONS

Tumors of Breast

Carcinoma of breast. The peak of age incidence in 2165 cases of cancer of the breast at the onset was about forty-seven years.¹²² The median age was fifty-two years, that is, as many cases occurred before that age as after it. Approximately a third of the patients were under forty-five years of age, another third from forty-five to fifty-five, and the remainder older than fifty-five. Taylor¹²³ found that about one third of the cases occurred during the period of mature ovarian function, another third appeared five years before and after the menopause and the remainder in women whose ovarian function had ceased five years or more. Thus, the two studies are in agreement but it must be pointed out that susceptibility to cancer of the breast steadily increases with age.¹²² Further data on the relation of breast cancer to the menopause were supplied by Olch.¹²⁴ According to his studies 72 per cent of normal women pass through the menopause from forty to fifty years of age, whereas 55 per cent of those with cancer are still menstruating at the age of fifty. It was concluded that almost five times as many women with breast cancer had a delayed menopause as compared with normal women. Data on the length of the menopause are not readily available. This may be of importance for, even though amenorrhea is one of the primary signs of the climacteric, the ovary may continue to be active and secrete estrogens for a relatively long period.¹²⁵ Since corpus-luteum function is usually diminished or absent during the menopausal years, the normal cyclic change disappears and estrogen stimulation may continue unopposed. Cancer of the breast may appear many years after castration, even when the latter has been performed at an early age. Estrogens presumably of adrenal origin are still recovered from the urine of patients who have been castrated, as well as from the urine of postmenopausal women.¹²⁵ Herrell¹²⁶ reviewed the records of a large number of patients in the same age group with and without cancer of the breast. The findings disclosed that in the cancer group the incidence of complete

ovariectomy before the tumor appeared was 1.5 per cent. The incidence in the noncancer group was 15.4 per cent, or ten times as great.

It is not known whether women who develop breast cancer have a higher percentage of menstrual disturbances than those who are free of the disease.¹²⁷ In one study, however, it was found that the menstrual pattern changed shortly before the discovery of the disease.¹²³ So far as can be determined there is no gross effect of the menstrual cycle on the primary tumor. The rapidity of growth of the primary tumor during pregnancy¹²⁸ and the appearance of a tumor in the second breast during another pregnancy,¹²⁹ which may ensue subsequent to treatment of the first lesion, is well recognized. Changes during lactation are usually more striking.¹²³ Whether these effects are caused by hormones elaborated in pregnancy or lactation or to the generalized metabolic changes has not been established.¹³⁰

Breast disease in general is frequently associated with disease or abnormalities of the uterus and ovaries, and in this respect cancer of the breast is no exception.^{123, 127} For example, Taylor¹³¹ found that cancer of the breast and endometrium may arise in the same patient. This information suggests that the entire reproductive system may be subject to the same abnormal stimulus. Nulliparous women have a higher incidence of cancer of the breast than those who have borne children.¹³² This appears to be the reverse of the situation in the mouse. Some believe that early weaning of the child or faulty lactation conduces to the development of breast cancer, in that they result in stasis and breakdown products which may cause chronic irritation.^{133, 134} A study of 350 children of women with breast cancer revealed that 72 per cent were nursed for at least six months and of the remainder, a small number were deliberately weaned or not nursed because of inadequate milk supply.¹²³ Further studies of lactation are indicated, since there is a possibility of an abnormal physiologic state that in itself predisposes to cancer.

The significance of a relation between certain types of chronic cystic mastitis and cancer is a subject of much controversy. Warren's¹³⁵ studies, which were confirmed by Logie,¹³⁶ demonstrate that the attack rate of breast cancer for women with chronic cystic mastitis in the premenopausal group (thirty to forty-nine years of age) was nearly twelve times greater than that of the general female population in the same period. After the age of fifty it

LABORATORY NOTE

A SIMPLE TECHNIC FOR RAPID SECTIONING

H. EDWARD MACMAHON, M.D.,* AND SHIRLEY B. DELVECHO†

CAMBRIDGE, MASSACHUSETTS

IN SELECTED cases the value of an immediate diagnosis at the operating table cannot be over-emphasized. The methods of obtaining this information vary. The usual procedure is to freeze tissue, cut a section with a microtome, stain it by dipping in staining solution, rinse it in water and mount it in water or gelatin. There are many minor modifications of this, which is not to be wondered at since the preparation of such sections is still customarily carried out by the pathologist rather than by his technician, and since each pathologist has adopted his own way of handling, cutting and staining tissues. Yet all these technics appear to rely on a microtome, a sharp microtome knife, a tank of carbon dioxide, a bottle of staining solution, glass rods, picks, brushes, staining dishes, rinsing dishes, filter paper, funnels, slides, coverslips and towels. Added to this list, in the case of the peripatetic pathologist, is an assortment of wrenches, wooden blocks and washers, and last but not least a stout, reinforced bag for carrying this equipment.

The following method has been successfully tried over a period of a year, and because of its simplicity it has a particular application to the work of the pathologist in the field. The procedure is so quick and so accurate that it warrants a trial. If one wishes to carry out the usual freezing technic as well, no time is lost, for the method here described can be completed during the few seconds that elapse while the tissue is being frozen for sectioning. It is quite inexpensive, for it eliminates the microtome, microtome knife, carbon dioxide, staining

solution and practically all the paraphernalia that have just been enumerated. The basis of this method is the staining of a thin layer of fresh, unfixed and unfrozen tissue, with a stain that, instead of being preserved as a liquid, is kept as a thin, dry film over the surface of an ordinary glass slide.

Some difficulty was encountered in obtaining thin even films, but this has been overcome by coating one surface of the slide with Mayer's albumen-glycerin mixture, a space being left at one end of the slide for handling, and dipping it for a few seconds in the staining solution—a 1 per cent aqueous solution of toluidine blue. The slide is then drained, the reverse side is wiped free of stain, and to ensure a uniformly stained surface the slide is left on a flat surface until dry. Several slides can be prepared at one time and kept indefinitely; they are always ready for use.

The only equipment required is a safety-razor blade, a prepared stained slide, a clean slide and a clean coverslip—all of which can be carried in a vest pocket. The technic is as follows:

- Cut a thin section that can be easily handled.
- Holding the section on the blade, gently place it on the ball of a finger.
- Draw the stained slide lightly and quickly across the section, staining only one surface of the tissue.
- Immerse the tissue in water.
- Mount the tissue on a glass slide with the stained surface up.
- Place a coverslip over the section, and with a good light examine the tissue.

The results of this technic have been as good as, if not better than, those obtained by the longer and more complicated procedures. It has been tried on breast tissue, lymph nodes, endometrial curettings, cervical tissue and fragments of rectal mucosa. During the trial period the accepted freezing method was used at the same time in each case, and as is the custom, permanent sections were ultimately prepared. In no case did the frozen-section or final report conflict with the original rapid-section diagnosis.

are as yet equivocal.¹²⁷ Observations suggest that the origin of fibroadenomas may be explained partially on the basis of endocrine dysfunction. It is also possible that they arise as a result of atypical stimulation, especially since they usually occur when the metabolism and secretion of the sex hormones are at their height and may be abnormal.

Tumors of Uterus

Cancer of cervix. Cancers of the cervix arise more frequently in multiparous women than those who have not borne children. Hofbauer¹⁵⁴ advanced the theory that the increased incidence of cancer of the cervix in this group resulted from intensive hormone stimulation during pregnancy rather than from birth injuries. The median age of cancer of the cervix is about forty-nine years.¹⁵⁵ It is not infrequent to find the disease in women passing through the menopause, when the symptoms may be attributed to the climacteric syndrome. Cancer of the cervix is occasionally associated with cancer of the breast and myomas of the uterus but less so than is carcinoma of the endometrium.¹⁵⁶ In our clinics, 3 women have developed metaplasia of the cervical epithelium after estrogen administration. The lesions regressed after treatment was discontinued in two patients, but in the third case an early cancer was diagnosed, which was subsequently confirmed by hysterectomy. Other observers have reported the development of cervical cancer in 3 of 43 patients treated by estrogens for senile vaginitis.¹⁵⁷ Yet other investigators failed to find such lesions after treating over 200 women with estrogens over periods varying from a half to five and a half years.¹⁵⁸ Hence, at the present time, the relation of these cancers to the estrogenic hormone is equivocal. In a considerable number of cases, cervical polyps have developed after estrogen administration to postmenopausal women. Hormone excretion studies to date are few, and no conclusions can be drawn from them.¹⁵⁶

Hyperplasia of endometrium. This lesion can be produced with comparative ease, especially in the absence of the ovaries in animals^{62, 64, 69} and in women,¹⁵⁹ particularly after the menopause. It arises spontaneously at the menopause in patients in whom ovulation is apparently deficient and in the presence of granulosa-cell or thecal-cell tumors of the ovary. These tumors frequently give rise to elevated titers of estrogenic hormone in the urine. Most investigators are of the opinion that the lesion is caused by continuous stimulation by estrogens that is unopposed by hormones possessing a balancing effect, such as the corpus luteum.¹⁵⁶ These assumptions are based on studies on patients in whom persistent large unruptured follicles have been found in the absence of a recent corpus luteum.¹⁶⁰ The histologic changes vary from a proliferation of the endometrium to those simulating early adenocarcinoma.¹⁵⁶ The fact that these

effects may be reversed by treatment with androgens and progesterone¹⁶¹ or following castration by either radiation or surgery further incriminates estrogens as the initiating factor. According to Taylor,¹⁵⁶ the origin of cystic hyperplasia of the human endometrium as a result of unopposed stimulation with estrogens on the basis of ovarian dysfunction may be regarded as established. He further points out that the finding of endometrial hyperplasia in conjunction with a tumor of the reproductive tract is presumptive evidence that estrogens are of some significance in the origin of the neoplasm as well. Regarding endometrial hyperplasia arising in the years after the menopause, the explanation is more difficult. As already pointed out, the estrogenic hormone may be found in varying amounts in the urine long after the menopause. Excretion studies of urinary estrogenic hormone suggest an increased urinary output, but these need confirmation.¹⁵⁶

Cancer of endometrium. This type of cancer is less frequent and usually occurs later in life than cancer of the cervix, suggesting that it may arise on a relatively senile endometrium. The median age in 331 cases was sixty-one.¹⁵⁵ According to statistical studies the disease is somewhat more frequent in nulliparous women and in those with a delayed menopause.¹⁶² Several cancers of the endometrium have apparently arisen after long-continued administration of estrogens.¹⁶³ This may very well be coincidence since it seems likely that more cases would have come to attention considering the sensitivity of the endometrium to the hormone at any age. Nevertheless there are now a fair number of cases reported in which endometrial cancer has been found in association with granulosa-cell tumors of the ovary. Taylor¹⁵⁶ points out that, in view of the rarity of these ovarian tumors, it is hardly conceivable that the associated endometrial lesion was merely coincidence. He states, therefore, that in these particular cases it is difficult to deny the sequence of increased estrogen stimulation, hyperplasia of the senile endometrium and, finally, cancer. Since endometrial hyperplasia is part of the picture, it is of interest to investigate the significance of this lesion as a precancerous change. Endometrial hyperplasia is fairly frequent, but endometrial carcinoma is relatively rare, and although some believe that hyperplastic changes are a predisposing factor, long-term studies of these cases have shown that few patients eventually develop cancer.¹⁵⁶ Furthermore, even though cancer is sometimes found arising in association with endometrial hyperplasia, some are of the opinion that such an occurrence is purely accidental. This is discussed in some detail by Taylor.¹⁵⁶ It must be remembered, however, that as in the case of the relation of chronic cystic mastitis to cancer of the breast, agreement concerning the histologic criteria is of importance. Finally, it is of interest to point

was two and five-tenths times as great, and for the entire group four and five-tenths times higher, suggesting that cancer may occur in association with or superimposed on the benign lesions during the period of greatest ovarian function.

Many have used castration as an adjunct to the treatment of cancer of the breast. This procedure is based on the work of Beatson,¹³⁷ who noted alleviation of signs and symptoms following castration in several women with cancer of the breast. Of late, x-ray therapy has usually been substituted for surgical extirpation of the ovaries.¹³⁸ The castration is of most value in premenopausal patients, although the effects are temporary, and seems to be of little benefit in the postmenopausal group. Bone metastases, as judged by x-ray examination, seem to regress partially or to disappear completely for a time. Relief from pain is frequently noted.¹²⁷ Effects on the primary tumor or lymph-node metastases are slight. It has been concluded that castration may be expected to result in temporary relief in about one third of the patients with extensive disease.¹³⁹ It cannot be demonstrated as *definitely advantageous when employed as a prophylactic procedure in patients submitted to the radical operation.* A report by Farrow and Adair¹⁴⁰ and an unpublished observation¹⁴¹ revealed similar changes in the osseous metastases and in the relief of pain after orchidectomy in males with cancer of the breast. In many cases, laboratory evidence reveals discrepancies regarding the efficacy of x-ray castration as compared to surgical removal of the ovaries.¹²⁵ X-ray was adequate in some cases, as judged by the urinary estrogen excretion, but in others fluctuations in the output appeared even though the patients became amenorrheic. Hence, it is essential that, if castration by x-ray is to be used effectively, factors such as the age of the patient and the size of the portal are important in determining an adequate dosage.

Three reports have appeared on the possible development of cancer of the breast in women after prolonged administration with estrogens.¹⁴²⁻¹⁴⁴ I know of at least 2 cases that have been associated with prolonged and intensive estrogen therapy. There is a good possibility that these were merely coincidental, but it certainly must be considered that the estrogens may have been contributory.

Attempts have been made to influence the course of cancer by the administration of hormones.¹⁴⁵ In our clinics, thus far, we have been unable to demonstrate a direct effect regarding augmentation or inhibition of the growth of the primary tumor by the injection of either estrogens or androgens. Farrow and Woodard¹⁴⁶ have noted that in the premenopausal group, skeletal metastases are apt to occur early. They also reported a marked acceleration of osseous metastases after intensive estrogen or androgen therapy. These changes were accompanied by an increased bone absorption and ele-

vations in the serum and urinary calcium levels. Several cases in our clinics treated in a like fashion showed the same changes. In the past few years, however, reports have appeared concerning beneficial effects following prolonged androgen^{147,148} and estrogen therapy^{149, 150} in cancer of the breast. Many of the cases treated with the estrogenic hormone were given x-ray therapy in addition, and the effects of the latter were considered to be enhanced by the hormone treatment. These reports of a satisfactory response to hormone therapy are exceedingly difficult to evaluate at present, because in some cases factors such as complete histories and histologic confirmation of the disease are lacking. Until these methods of therapy receive further trial under carefully controlled conditions in large clinics, the subject must be left entirely open.

Excretion studies of the hormones with the present methods have failed to yield much information.¹²⁷ Several conclusions, however, may be drawn from such investigations: there is no significant deviation in the excretion of sex hormones in women with breast cancer: there is no proof that sex hormones are not involved in the disease or that abnormal secretion of the hormones does not accompany or precede the development of breast cancer—it is significant that normal excretion rates may be found in the presence of breast cancer; and cancer of the breast may be independent of hormonal influence once it develops.

The available evidence from all sources leads one to conclude that definite proof for the hormones as the direct cause of cancer is lacking. It is possible that in some cases they may be indirectly responsible by producing a fertile soil for the disease to develop.

Fibroadenoma of breast. These tumors seldom arise before puberty or after the menopause. Generally they are detected in the second and third decades. The lesions are usually slowly growing, and although they may pass unnoticed for a long time, it is possible that they arise in the early years after the menarche, when atypical menstrual activity is not infrequent. The disease is said to occur oftener in persons of a definite constitutional type, namely, nulliparous women with a relative underdevelopment of the pelvic organs and breasts.¹²³ The menstrual cycles are seldom abnormal when the patients are first seen, although some give a history of a period of abnormal cycles following the menarche.¹²⁷ Definite changes have been observed, however, in the size and the histologic appearance of the tumors during the menstrual cycle¹⁵¹ and during pregnancy and lactation.^{152, 153} Estrogens have been given over a long period to patients in the presence of and following the removal of fibroadenomas.¹²⁷ No new tumors have been observed that could be attributed to the hormone, since additional lesions frequently arise spontaneously. The significance of excretion studies of the sex hormones

seems to be directly related to the secretory activity of the gland.¹⁸⁴ Serum-acid phosphatase levels are frequently elevated in patients with cancer of the prostate, particularly those with bone metastases.^{182, 185-187} Serum-alkaline phosphatase levels are also above normal in many cases in which osseous metastases are part of the clinical picture.¹⁸² Excessive acid phosphatase can be demonstrated by histologic examination of neoplastic prostatic tissue.¹⁸⁸ Dean, Woodard and Twombly¹⁸⁹ state that patients may be placed in four groups, based on the serum-phosphatase levels:

Normal men in whom there is no increase in either the serum acid or alkaline phosphatases. It is noteworthy that since every adult prostate contains large quantities of acid phosphatase and that the serum acid phosphatase of men is the same as that of women, who have no organ rich in acid phosphatase, this substance is prevented from entering the circulation by an intact prostatic capsule.

Patients with cancers of the prostate and normal amounts of serum acid and alkaline phosphatase. In this small but definite group one may operate with an excellent chance of removing all of the disease because the tumor probably has not grown beyond the gland.

A group consisting of the great majority of patients with prostatic carcinoma. The tumor has grown through the gland capsule and there may or may not be distant metastases. In our experience 73 per cent of these patients show increased serum acid phosphatase.

Patients with prostatic cancers which metastasize to bones. There is nearly always an increase in the serum alkaline phosphatase in these cases. The quantity of this substance in the serum so accurately represents the amount of reaction of the bones to the invasion of prostatic carcinoma that quantitative assays give clinical information not obtained by any other tests, such as the roentgen rays.

Castration and injection of estrogens produce little change in the acid phosphatase level if it is normal before such therapy.¹⁸⁹ Castration and injection of estrogens, however, into patients with prostatic cancer having marked elevation of the acid phosphatase result in a sharp reduction of the levels of the enzyme, but seldom to normal.¹⁹⁰ Administration of androgens produces a sharp rise in the serum acid phosphatase.¹⁹⁰ Alkaline phosphatase following castration or injection of estrogens into patients with metastatic disease may rise, show no change or decrease, either at once or after a latent period.¹⁸⁹ These observations have been of inestimable value in the diagnosis of the extent and recurrence of the disease.

Castration or the administration of estrogens, or both, produce apparent regressions of the prostatic lesions and their metastases in many patients.^{188, 189, 191-193} Serial biopsies of the tumor reveal marked degenerative changes in the cells when stilbestrol is given over a fairly long period of time.¹⁹⁴ Administration of androgens seems to increase the activity of the process.^{190, 195}

Excretion studies of the sex hormones in the untreated case before and after castration or hormone administration are of interest. Following castration a decreased estrogen excretion has been reported, whereas the 17-ketosteroids (androgens) after a slight initial fall may rise above the pre-

treatment level.^{189, 195, 196} Pituitary gonadotropin increases in the urine following castration, as is the case in menopausal or castrated women or in men who have undergone the climacteric. Injection of estrogens may decrease the 17-ketosteroids and pituitary gonadotropic levels in the urine, and the urinary estrogen titers may rise.¹⁸⁹ Thus it appears that the mechanism by which these two methods produce their similar beneficial effect may be somewhat different. The primary effect in the case of estrogen therapy seems to be on the tropic functions of the anterior pituitary gland, which are inhibited and in turn result in decreased stimulation of the organs that may produce androgens (gonads and adrenal glands). Castration, although removing one source of androgens, allows for increased pituitary activity, which may stimulate other organs, such as the adrenal glands, to increased androgen production.

Concerning the therapeutic value and marked clinical improvement following castration or estrogen administration, or both, there can be no doubt. It is still unsettled which form of therapy is the best. Castration or estrogens alone or in combination either simultaneously or successively all have their adherents. The greatest hopes for the treatment, however, have not materialized. Certain cases do not respond to treatment at all, whereas others show striking clinical improvement and relief from pain. This may be related to the histologic type of tumor, since those lesions that more nearly resemble the adult gland seem to respond best to the therapy.¹⁹³ It has also been conceded that the treatment in itself cannot be considered a curative procedure but should be reserved for palliative purposes. To date, there is no substitute for radical surgical procedures in operable cancer of the prostate without metastases. On the basis of present evidence, castration or hormone therapy should not be resorted to as the primary treatment in this type of case. Most patients who benefit from castration or estrogen therapy have recurrence of the signs and symptoms within a few years and many are not relieved for more than a few months.^{189, 193, 197} Some patients live without symptoms or obvious signs of activity of the disease for long periods of time, but as yet there is no definite evidence of true curability. It must be remembered that cancer of the prostate varies in its course and degree of malignancy so that the untreated patient or those receiving palliative surgical measures may live for a long time without benefit of any other form of therapy.¹⁵⁵ The final answer must await longer periods of observation.

Tumors of Testis

Tumors of the testicle are essentially diseases of the young. Approximately 75 per cent of the lesions arise in patients under the age of forty, and the average age incidence is about thirty-five.^{155, 198}

out that cancer of the endometrium is oftener associated with cancer of the breast and fibromyomas of the uterus than is cancer of the cervix.^{156, 164, 165} Hormone-excretion studies of significance in this disease have not been reported.

Fibromyomas. Many believe that fibromyomas of the uterus result from ovarian dysfunction. This is based particularly on the association of follicle cysts and endometrial hyperplasia with the disease, thereby suggesting excessive estrogenic stimulation,¹⁶⁶ but weighty evidence suggests that this is not the case. For example, Meyer¹⁶⁷ stressed that patients with fibroids become pregnant, menstruate normally and undergo typical cyclic changes, all of which is against ovarian dysfunction as a cause of the disease. It is well known that a certain number of lesions regress after the menopause or castration. This is far from constant and, as has been pointed out, may be related to the blood supply, especially since fibroids with adhesions to extrapelvic organs may continue to grow.¹⁶⁶ There are reports on the regression of fibroid tumors after treatment with testosterone and progesterone, but these are difficult to assess. A study of the excretion rates of the sex hormones in this disease failed to reveal any gross abnormalities.¹⁶⁸ Thus far the only convincing evidence for a hormonal etiology is the regression of the tumors after ovarian activity has ceased.

Tumors of Prostate Gland

Hypertrophy of prostate gland. Benign prostatic hypertrophy, that is, nodular hyperplasia, occurs in men over forty years of age. The disease increases with advancing age, so that between the ages of eighty and ninety, 75 per cent of men have some degree of nodular hyperplasia.¹⁰⁸ Obstructive symptoms, however, reach a maximum at about sixty-three years. As suggested by Moore,¹⁰⁸ this may mean that the etiologic agent becomes active after forty years of age, reaches its maximum soon after sixty and then decreases in intensity, but still remains capable of producing additional or new nodules. Some statistics indicate that benign hypertrophy is less frequent in single men.¹⁶⁹ Nodular hyperplasia of the prostate does not occur in the posterior lobe. Moszkowicz¹⁷⁰ showed that the structure of the prostate in the pseudohermaphrodite is dependent on the type of gonad present: the prostate is composed only of the middle and lateral lobes in the presence of ovaries, whereas in the presence of testes the entire prostate is found. These observations indicate that the posterior lobe is primarily a masculine organ, whereas the other lobes are ambisexual, that is, they can be stimulated by both estrogens and androgens.¹⁰⁸ There is no direct relation between the histologic appearance of the testes and benign prostatic hypertrophy. A survey of the literature by Moore¹⁰⁸ revealed, however, that, in a series of 28 eunuchs, eunuchoids

and those with pituitary infantilism in whom the secondary sex characteristics were lost before the age of forty, there was not a single case of the disease, even though they all lived to be over forty-five years of age. The incidence would be quite high in a similar age group in the normal population. Hence, it appears that the disease does not develop in the absence of the testes.

The changes in the prostates of patients with testicular tumors are not consistent. Cases occur in children in whom signs of adrenal insufficiency are accompanied by those associated with adrenal hyperfunction, particularly the masculinizing syndrome. In these children there is a hyperplasia of the prostate gland similar to what occurs in adults with functioning adrenocortical tumors.¹⁷¹ In primary Addison's disease the prostate does not differ from that in normal subjects.¹⁰⁸ Estrogens and androgens have been used in the treatment of benign prostatic hypertrophy, and although beneficial effects are said to occur, the consensus at present is that they are infrequently of any value.¹⁷² Castration has also been reported as beneficial, but this too is controversial.¹⁷³ Excretion studies of the sex hormones suggest a decrease in androgens and estrogens in those patients as contrasted with the levels in normal men of the same age.^{174, 175} Thus these observations, although not conclusive, suggest an endocrine dysfunction as a possible etiologic factor in the disease.

Cancer of prostate. The median age at the onset in 235 cases with cancer of the prostate was sixty-five.¹⁵⁵ It is rare below the age of thirty and increases steadily with advancing age. In fact in the eighth decade of life it is one of the most frequent of all carcinomas.¹⁷⁶ Prostatic cancer is rare in the Chinese¹⁷⁷ and has not been recorded in eunuchs or eunuchoids.¹⁰⁸ Routine autopsy studies of the prostate in man reveal an incidence of 10 to 15 per cent of latent carcinoma.¹⁷⁸⁻¹⁸⁰ On one series of unselected consecutive autopsies on 50 men over fifty years of age, however, the prostate was examined by serial section and the incidence of occult carcinoma was 46 per cent, although prostatic carcinoma was not the cause of death in any case.¹⁸⁰

Following the progress report of Quinby¹⁸¹ in 1942 more material has accumulated, and it may be of interest to bring this up to date. Although castration was previously suggested and occasionally used as a treatment for cancer of the prostate, it was not until the excellent work of Huggins and his group^{109, 110} on the effect of the hormones on the prostate and that of the Gutmans¹⁸² on acid phosphatase that investigation of the hormonal relation to the disease received a real stimulus. The prostate in childhood contains small amounts of acid phosphatase, but the level rises considerably after puberty.¹⁸³ This enzyme, which is present apparently in large amounts only in the prostate,

hormone excretion is of the greatest value in patients who have functioning tumors of the adrenal glands and the gonads, such as adrenocortical hyperplasias, adenomas and carcinomas, granulosa-theca-cell tumors of the ovary, arrhenotomas, and teratoid tumors and interstitial-cell tumors of the testes. The excretion rates in these cases are of inestimable help in making the diagnosis and in following the course of the disease. Recent studies on the isolation of the sex hormones suggest that patients with cancer may excrete estrogens and 17-ketosteroids in a different fashion from persons without cancer. The usual relation of the individual components of both the estrogens²⁰⁸ and 17-ketosteroids^{209, 210} may be atypical as well as the ratio between the total estrogenic and 17-ketosteroid complexes. It is clear that alterations in excretion levels or in the specific type of hormone excreted are not necessarily characteristic of patients with cancer. They may merely represent deviations from normal that occur only as a result of disturbed metabolism in the sick person. They indicate, however, a distinct abnormality, and as such are significant in the study of the disease.

CONCLUSIONS

A considerable number of data bearing on the relation of the endocrine organs to tumors have accumulated. The administration of sex hormones to experimental animals has resulted in the production, the augmentation and the inhibition of benign and malignant tumors. These changes are limited to definite types of tumors in different species, as well as to certain strains in any one species of animal. Thus, there are other factors that determine the reaction of a tumor to a hormonal stimulus, and the susceptibility of an animal to the induction of a neoplasm. It is difficult to interpret these facts in terms of human cancer. Nevertheless, they are of extreme importance in the study of the origin and course of cancer in general.

Strong evidence exists to indicate that endocrine factors are associated with some human tumors. There is as yet no conclusive proof that these influences are directly concerned with cancer, although an increasing number of cases are coming to light in which cancer developed after intensive estrogen therapy in organs such as the uterus and breast, which are normally stimulated by these hormones. It is probable that this is coincidence, but the association cannot be ignored. Present evidence suggests that the sex hormones are not in themselves carcinogenic. It is likelier that, as a result of excessive stimulation or atypical metabolism, the tissues of susceptible persons are conditioned to the action of a carcinogenic agent.

There is little to support the therapeutic value of hormones in the treatment of any cancer except that of prostatic origin. Judgment must be re-

served until much more information is obtained regarding the treatment of cancer of the breast or other organs with either estrogens or androgens. There is no question that castration as an adjunct to the treatment of selected cases of cancer of the breast and prostate and the administration of estrogens to patients with cancer of the prostate have been of great benefit. Such treatment should be reserved for palliative purposes only, since there is at present no substitute for established methods of surgery and radiation in the operable patient. Indiscriminate use of the sex hormones may also produce untoward effects in other ways. It therefore behooves all to be extremely cautious in the use of the sex hormones for any syndrome, even when the indication for treatment is well defined.

In other words, these tumors appear at a time when the male is most active sexually. This age incidence is distinctly different from that of most other types of malignant neoplasm and suggests causation by other agents. It is also well recognized that tumors of the testicle occur more frequently in men with undescended testes. Gilbert and Hamilton¹⁹⁹ found that in 345 of 835 reported cases of teratoma of the testicle the lesions were intra-abdominal. Eleven per cent of the 345 occurred in pseudohermaphrodites. This does not mean that when unilateral cryptorchidism is present the tumors always appear in the undescended testis. In one study it was found that the tumor occurred in the normal gonad in 23 of 744 patients with unilateral cryptorchidism,¹⁹⁹ and in another series the incidence was 6 in 27 cases.¹⁹⁸ These findings, however, suggest a possible hormonal factor.

Excretion studies of the hormones are of great interest in tumors of the testicle. Gonadotropic substances are often excreted in increased amounts in the urine of patients with testicular tumors.²⁰⁰ Two types have been identified — one similar to the chorionic gonadotropin normally found in the urine of pregnant women,²⁰¹ and the other a gonadotropin similar to that found in human beings who have been castrated or who have passed through the menopause.²⁰² The latter will be referred to as the pituitary type of gonadotropin. Some malignant tumors of the testes, although histologically similar to those resulting in increased secretion of gonadotropins, fail to show any increase; clinically such cases behave identically with those in which the hormone titer is elevated.^{198,202} Furthermore, as pointed out by Hamburger²⁰² and by Twombly,¹⁹⁸ the pituitary type of gonadotropin may be present in increased quantities in the urine in the absence of active tumors. It does not vary with treatment or progression of the disease. Although it was formerly thought that the amount of hormone excreted paralleled the degree of malignancy of the tumor, it has recently been shown that this cannot be relied on to be pathognomonic of cell type, any more than can the nature of the hormone excreted.²⁰³ In general, however, chorionic gonadotropin is likelier to be associated with embryonal adenocarcinomas and chorioepitheliomas, whereas elevations of the pituitary type of hormone usually accompany seminomas, there being exceptions in both groups. Both hormones are often found in the same patient, which suggests that many testicular tumors consist of mixed cell types.^{198, 204, 205}

These hormone studies are of interest in prognosis. It has been stated that cases showing unusually large amounts of the hormones in the urine have a poor prognosis. Hamburger, Bang, and Nielsen²⁰¹ based their observations, however, on differentiation of the two forms of hormones excreted. They are of the opinion that the chorionic type is secreted by the tumor, since this hormone is biologically similar

to that secreted by the normal placenta. Moreover, there appears to be a close correlation between the amount excreted and the extent of the neoplastic disease. Twombly¹⁹⁸ states that this type of hormone in male urine does not appear except when tumor is proved to be present. Several observers agree that the chorionic gonadotropin is likely to be indicative of a radioresistant type of tumor, whereas tumors associated with an increased excretion of the pituitary type of gonadotropin are usually radiosensitive.²⁰⁴ Excretion studies are also of value in studying the course of the disease. If there are no metastases and the tumor is secreting large amounts of hormones, orchidectomy will usually be followed by a prompt disappearance of the hormones. If metastases appear subsequently, the hormone levels may again rise, and in some cases may predict recurrences before they can be detected clinically. If metastases are present at the time of orchidectomy the titer may show little change. The effectiveness of x-ray therapy in the metastatic lesions in some cases may also be determined by a study of the excretion rates.

Abnormal estrogen excretion may be found in the presence of these tumors, particularly those that produce large amounts of chorionic gonadotropin.¹⁹⁹ Pregnandiol, the excretion product of the corpus luteum hormone, was also found to be elevated in one case of chorioepithelioma.¹⁹⁸

The excretion of biologically active androgens is definitely decreased in a high percentage of seminomas.²⁰⁶ In cases showing chorionic gonadotropin, levels below normal were found in about half the cases studied. Hamburger and Godtfredsen²⁰⁶ believe that the formation of chorionic gonadotropin may stimulate the remaining testis and the adrenal glands, causing the production of male hormone. This might explain the difference in the findings between these two types of tumors.

Attempts to influence the course of testicular tumors by hormones have been made by Twombly.¹⁹⁸ Administration of antigonadotropic principles resulted in the increase of the hormone titers. Estrogens were also tried on 2 patients without any striking change. Saleeby²⁰⁷ suggested that bilateral gonadectomy should be done and cites a case in which the patient seemed to improve after the procedure was carried out. Evaluation is complicated, however, by the fact that the patient had x-ray therapy as well.

SIGNIFICANCE OF HORMONE EXCRETION

Urinary excretion levels of the sex hormones represent only the end product of metabolism. It is not definitely known whether they give true indices of the blood levels, the rate of secretion or destruction and the utilization of the hormones by the tissues. Furthermore, they do not reveal the exact nature or relation of the various components of the hormones excreted. Thus far, the study of

CASE 30501

PRESENTATION OF CASE

First admission. A forty-nine-year-old electrician was admitted to the hospital with substernal pain of twenty-four hours' duration.

The patient was well until the day before admission, when he suddenly developed a sensation of breathlessness and a lump in his throat. This

mission the pain appeared to be epigastric, radiating to the top of the sternum. For five years prior to admission the patient had had attacks of "indigestion" associated with pain radiating to the head and with spots before the eyes.

Physical examination revealed a well-developed and well-nourished, restless man complaining of substernal pain. The skin was dry, and the heart, lungs and abdomen were normal.

The temperature was 100°F., the pulse 68, and the respirations 16. The blood pressure was 140 systolic, 90 diastolic.

Examination of the blood showed a red-cell count of 5,000,000, with 17.5 gm. of hemoglobin, and a white-cell count of 15,000, with 80 per cent neutrophils. The urine and stools were normal. The erythrocytic sedimentation rate was 24 mm. per hour, total fall (0.8 mm. per minute, corrected). The serum cholesterol was 292 mg. per 100 cc.

An electrocardiogram taken on admission re-

FIGURE 1. Electrocardiogram during the Acute Anterior Myocardial Infarction in 1942.

lasted a few moments and was followed an hour later by a squeezing sensation beneath the sternum, with pain radiating to the deltoid region and down the extensor surface of the right arm. This was accompanied by nausea and a recurrence of the feeling of breathlessness. A physician gave him "an injection and some pills." He vomited eight times during the night. On the morning of ad-

mission the pain appeared to be epigastric, radiating to the top of the sternum. For five years prior to admission the patient had had attacks of "indigestion" associated with pain radiating to the head and with spots before the eyes.

The patient was treated with morphine and bed rest and quickly became asymptomatic. The temperature fell to normal on the fifth hospital day, and the white-cell count gradually fell to 7600 over a period of about two weeks. The corrected sedimentation rate gradually fell to 0.6 mm. per minute. A subsequent electrocardiogram (Fig. 1) showed

apex posteriorly. There was slight tenderness in the left lower quadrant of the abdomen. The knee jerks were hypoactive, and the Babinski positive bilaterally.

and the protein 6.7 gm.; the chloride was 94 milliequiv. per liter.

On the evening of admission the patient coughed up thick orange-colored sputum for the first time.

changes characteristic of involution of a large anterior-wall infarction with prominent Q waves and inverted T waves in Leads 1 and 4. He was discharged on the forty-second hospital day.

Second admission (eight months later). Following discharge the patient was followed in the Out-Patient Department, where he showed progressive improvement. He continued to have slight precordial pain, however, with mild choking sensations and dyspnea.

Two nights before his second admission, after a day of unusual exertion, he suddenly developed severe substernal pain radiating down both arms

version of the T waves in Leads 1 and CF₄. A subsequent tracing (Fig. 3) showed a return to normal rhythm, and the remaining changes were considered characteristic of the evolution of a posterior-wall infarction. The temperature and white-cell count rapidly returned to normal. He was discharged on the thirty-fifth hospital day.

Final admission (one year later). Following discharge the patient was unable to work and remained at home. An electrocardiogram two months after discharge (Fig. 4) showed normal rhythm at a rate of 100, with small Q waves and low T waves in Leads 1, 2 and 3 and fairly normal tracings in

FIGURE 2. Electrocardiogram during the Acute Posterior Myocardial Infarction in 1943.

and relieved by nitroglycerin. He spent a restless night in moderate discomfort and remained in bed the following day. On the evening before admission a similar but severer attack occurred, which was accompanied by a sense of suffocation.

On admission the physical examination was negative except for an inconstant gallop rhythm at the apex, thought to be systolic. The white-cell count was 19,600, with 89 per cent neutrophils.

On admission, the temperature was 96.4°F., rapidly rising to 102°, the pulse 54, rising to 100, and the respirations 20. The blood pressure was 160 systolic, 100 diastolic.

An electrocardiogram (Fig. 2) showed 2:1 auriculo-ventricular block, with a ventricular rate (R) of 50 and an auricular rate (P) of 100. Q₁ and Q₂ were small. There was depression of the ST segments in the precordial leads (CF₂, CF₄ and CF₅), with elevation in Leads 2 and 3. There was late in-

version of the T waves in Leads 1 and CF₄; it was much more normal in appearance than the previous records (Figs. 1, 2 and 3). He had, however, frequent attacks of pain in the right wrist radiating up the arm and across the upper chest, usually precipitated by slight exertion but occasionally occurring while at rest; these were relieved by nitroglycerin. On the day before admission he had such an attack; it was extremely severe and was relieved by nitroglycerin only for brief periods. Several hypodermic injections gave no relief. He also noted a dull pain over the lower right chest anteriorly. He felt weak and was dyspneic. During the night the pain in the arms and chest continued. He developed a dry hacking cough, was nauseated and perspired freely. He was admitted to the hospital the following morning.

Physical examination revealed an acutely ill, cyanotic man with warm, moist skin and rapid.

The onset of pain on the final admission seemed to be similar in nature to the pain that he had had during the year previous to entry. It makes one think seriously of the possibility of his having had a third myocardial infarction. We might follow that line of reasoning and say that with this attack he went into congestive failure, that he developed edema of the lungs and diminished urinary output, with nitrogen retention, and that he had cerebral anoxia. That might have accounted for the positive Babinski and the increasing disorientation. We might go farther and say that he developed bronchopneumonia, which was responsible for the fever.

I think we ought to review the findings at the time of the last admission to see if there is anything against that diagnosis. The first thing is the dull pain over the right lower chest anteriorly. I do not consider this as being typical of the pain of myocardial infarction. I did consider the possibility of small pulmonary infarcts. In the examination of the heart I was surprised that he did not have gallop rhythm. This might have been present but not detected. I cannot explain tenderness in the left lower quadrant of the abdomen on the basis of recent myocardial infarction, and I do not know whether it is significant. I should think that the positive Babinski in a fifty-year-old man, even if he did have considerable anoxemia, is a rather unusual finding, and possibly one ought to consider some other lesion of the brain. The rise in the non-protein nitrogen can reasonably be explained on the basis of the fall in blood pressure and a certain amount of nephrosclerosis. Concerning the culture of the sputum, I do not know whether the few beta-hemolytic streptococci have any significance. It must be considered, however, in the face of the high temperature. Curiously, the first chest film showed a normal-sized heart and a few days later another film showed an enlarged heart.

Perhaps this would be a good time to look at the films.

DR. MAURICE FREMONT-SMITH: How far apart were the examinations?

DR. LAURENCE L. ROBBINS: Four days; but the last film was so poor that I did not put it up. The heart is probably enlarged in this film, but the film was taken anteroposteriorly instead of postero-anteriorly, and I am not impressed with the size of the heart. There is increased density in both upper lung fields and in the middle portions of the lower lung fields. These areas are clearer on the last film, but I still think that there is some increase in density; it is not particularly well defined, but there are mottled areas scattered throughout.

DR. HARWOOD: Are they characteristic of any lesion?

DR. ROBBINS: They could be pulmonary infarcts but they certainly are not typical; they could be caused by congestion.

DR. HARWOOD: The electrocardiogram showed little change considering the pain. I do not set

myself up to be an expert on this type of examination, but I believe that this patient had marked changes in the ST segment in the T waves in both of the previous attacks. If this were a fresh infarction, I should expect to see more than an inverted T₁ after six days. Will you comment on that, Dr. White?

DR. PAUL D. WHITE: On the first admission in 1942 the record was absolutely characteristic of anterior myocardial infarction in both the limb leads and the precordial leads (Fig. 1). On the second admission, in 1943, a year before the patient died, he had absolutely typical evidence of posterior myocardial infarction superimposed on the changes due to the anterior scar (Fig. 2). It is interesting that he had heart block the second time; this is more frequently found after posterior myocardial infarction with thrombosis of either the left or the right circumflex vessel. The heart block cleared up entirely, as it usually does (Fig. 3). During his convalescence from the second myocardial infarct the electrocardiographic leads looked much better than after the first infarct. A neutralization of the "bad" features of the electrocardiogram that resulted from the first attack was effected by the second attack, even though there was actually more heart disease, for the reason that the T waves became upright again in both Lead I and in the precordial leads, as is shown in Figure 4, an electrocardiogram taken two months after the second attack. After posterior infarction the record never looks so "bad" as after anterior infarction, since inversion of T₁ may occur normally and does not appear so abnormal as inversion of T₁. The neutralization effect of the two lesions, front and back, was more or less maintained at the time of the last admission, and it becomes rather difficult to say from the electrocardiogram (Fig. 5) what happened at that time. Clinical evidence becomes all the more important because of this very difficulty. The limb leads show lower voltage without any especially acute changes in the T waves or ST segments but there is some change in the QRS waves, especially in Leads 2, 3, CF₄ and CF₁, and there is a simple tachycardia superimposed. The combination of lesions that had occurred before might explain the majority of the abnormalities in these last electrocardiograms. There were still fairly good precordial leads, except for the QRS waves in Leads CF₄ and CF₁ on the final admission, and the T waves and ST segments were better than those at the time of the other two admissions. One great difficulty is that, when one has coronary heart disease, anything that disturbs the circulation functionally can also cause changes in the electrocardiogram that are not necessarily due to structural damage.

DR. HARWOOD: It seems to me that we have to decide whether this patient had a fresh infarction, with resulting congestive failure, and terminal bronchopneumonia, or whether he had some other event, such as infection or pulmonary infarction,

culture of which revealed a few beta-hemolytic streptococci. A roentgenogram of the chest revealed increased density in both upper lobes and in the medial portions of both lower lobes; this showed some clearing four days later. The heart appeared normal. An electrocardiogram (Fig. 5) showed sinus tachycardia of 120, with low T waves in all leads. The QRS waves in Leads 1, 2 and 3 were low in voltage. This was not significantly different from a tracing taken nine months before, but wide Q waves had appeared in Leads CF_4 and CF_5 . Six days later T_3 was slightly inverted.

The patient was treated with tourniquets, oxygen, morphine and Cedilanid, with some initial improve-

ment. The temperature continued to rise, however, eventually reaching $104.8^{\circ}F.$, with a pulse of 140 and respirations of 50. The serum nonprotein nitrogen rose to 110 mg. per 100 cc. The lung signs cleared considerably, but the patient became increasingly disoriented. An x-ray examination of the chest at that time revealed an enlarged heart with a rather diffuse haziness over both lung fields suggestive of pulmonary edema but with no frank area of pneumonia. His respirations became acidotic, and he died on the seventh hospital day.

Then we come to the final admission one year later. I should like to ask about the acidotic respirations. Since the man had rapid labored breathing on admission and some evidence of congestive failure, I should like to know how one can differentiate the type of breathing.

DR. ROBERT L. BERG: I saw the patient, and I believe that he had not only rapid and shallow respirations but also a uremic odor to his breath.

FIGURE 5. Electrocardiogram Taken in 1944, the Year after the Second Attack and One Day after the Onset of the Final Illness.

DIFFERENTIAL DIAGNOSIS

DR. REED HARWOOD: The first two admissions in this case can be summarized briefly. At the age of forty-nine, twenty months before death, this patient came into the hospital with a history, physical examination and electrocardiographic findings typical of a large anterior myocardial infarction. On the second admission, eight months later, the patient

had a similar episode, the electrocardiograms being classic for posterior myocardial infarction. The only other thing worth mentioning in the initial admission is that he had a serum cholesterol of 292 mg., which is rather high.

DR. HARWOOD: Then we have to qualify that statement. It might have been actual dyspnea, with a uremic odor to the breath.

I am also interested in the urinalyses. The only one reported was done at the time of the first admission, and that was negative.

DR. BENJAMIN CASTLEMAN: The urinary sediment showed 2 to 12 white cells and an occasional epithelial cell per high-power field. There was no albumin or sugar. On admission he had a +++ test for acetone, but that disappeared. The specific gravity was 1.034 on admission, and 1.020 and 1.024 after that.

DR. HARWOOD: May I ask about the urinary output during his final stay in the hospital?

DR. CASTLEMAN: You may look at the chart.

DR. HARWOOD: The output was 500 cc. in the first twenty-four hours, and rose to 1500 cc. on the fourth day; it was 1250 cc. on the next day, and fell off to 300 cc. on the last day.

DR. WHITE: Human electrocardiography began with chest leads; the first record ever published, and probably taken, was by Waller¹ in 1887, who placed one electrode on the front of the chest and one on the back. The capillary electrometer then used was exceedingly clumsy, and it was not until the string galvanometer was introduced in 1903 by Einthoven² that clinical electrocardiography became feasible.

In those early years it was the custom to take the limb leads, for convenience largely, but when certain electrocardiographers like Lewis³ wanted to explore the thorax to get better records of auricular action, they did put electrodes over the heart, chiefly over the sternum in the region of the right auricle. In the course of time a number of investigators explored the chest, including Dr. Burwell and myself,⁴ in the search for other planes than the frontal for determination of the projection of the electrical axis. Dr. Burwell and I wanted to study, for example, the electrical axis in space to get more idea of the size of the left ventricle. This did not pan out at the time because we did not appreciate the importance of the proximity of one of the electrodes to the heart itself.

As time went on, Wilson⁵ in Ann Arbor and Wood⁶ and Wolferth⁷ in Philadelphia studied leads taken with electrodes placed on the chest directly over the heart. It has been found that direct leads from the heart itself show best the condition of the underlying myocardium and that next best are the leads taken from the chest wall as near as possible to the heart. Thus some ten or twelve years ago precordial electrocardiography began.

In the early days of clinical precordial electrocardiography its application was rather hit or miss; often just one electrode was applied and that, as a rule, was placed at the apex of the heart; in fact, this apical lead, with the other electrode placed on one of the extremities, became the recently current, and still customary, Lead 4. This apical lead has often been extremely helpful, being abnormal in some cases, especially those of coronary heart disease, in which the usual limb leads (Leads 1, 2 and 3) are normal, but such a finding is dependent on the proximity of the cardiac damage to the exploring electrode, whereas lesions elsewhere or abnormalities of the heart chambers other than that of the ventricle directly underlying the electrode are likely to be missed when only one single precordial lead (Lead 4) is taken.

During the last ten years a great deal of study has been carried out using multiple precordial leads, but much of this is still in the investigative stage. Precordial leads, however, have been numbered so that physicians will know about what the cardiologists are talking. The first precordial lead point is just at the right of the sternum in the fourth intercostal space. The second precordial lead point is just to the left of the sternum in the fourth inter-

costal space. The third precordial lead point is midway between the second and fourth on a direct line, the fourth being not necessarily the same as the routine Lead 4 but placed in the midclavicular line, usually in the fifth interspace on a line between the second precordial lead point and the cardiac apex. The fifth precordial lead point is on a horizontal line from the fourth in the anterior axillary line, and the sixth is in the midaxillary line. Other lead points have been suggested, such as a seventh in the posterior axillary line or at the angle of the left scapula and so forth, but we recognize officially only these six leads at the present time. The indifferent electrode, that is, the other electrode, can be placed either on the right arm (when we speak of the precordial leads as CR₁₋₆), on the left arm (when we speak of the precordial leads as CL₁₋₆), on the left leg (when we speak of the precordial leads as CF₁₋₆), or on a junction point of the three, Wilson's lead, in which the effect of any one extremity is neutralized by the others (when we speak of the precordial leads as CV₁₋₆). Thus, actually twenty-four precordial leads may be taken.

We have made a special study of about 175 cases, normal and abnormal, using these twenty-four precordial leads and have learned a good deal, but of course, they are not applied routinely. In fact, a good many cases need no precordial leads. In doubtful cases, especially those in which coronary insufficiency or massive pulmonary embolism is suspected, in cases of hypertension and coronary heart disease and for complete examination, precordial electrocardiography is in order.

Finally, we come to the practical application of these various precordial leads to clinical electrocardiography. Two reports have been published by the American Heart Association through its Committee for Standardization of Precordial Leads,^{8,9} but neither of them is final because there has been no exact agreement concerning which precordial leads are to be advised. It is the consensus among experienced electrocardiographers that more than one precordial lead is important in order to see what is going on over the right ventricle, as well as over different parts of the left ventricle and the septum. In the last report of the American Heart Association three precordial leads were advised, namely, C₁, C₂ and C₃. We, however, and a number of others, have found that it is more practical and of greater value to use C₂, C₄ and C₆, which, as a rule, are located as follows: C₂ over the right ventricle, C₄ at the junction of the right and left ventricle, and C₆ over the left ventricle. It is astonishing how much difference there often is between C₄ and C₆ if C₄ is over the right ventricle and C₆ is over the left, or if one of these leads has a lesion directly underneath it. For the indifferent lead point we prefer the left leg. One is likelier to find abnormalities with that connection than with the others, although there are

that by increasing the strain on the heart produced both coronary and myocardial failure. I am inclined to favor the latter, on the basis of the rather unusually high temperature and the rather minor signs or change in the electrocardiographic tracings.

Before closing I should like to mention two other possibilities that seem rather unlikely. One is a dissecting aneurysm, in which one would expect the blood pressure to stay much higher and the pain to be much worse. One would also expect to find evidence of circulatory changes in the extremities. I am going to exclude it. An extremely rare possibility is rupture of the heart through an aneurysm resulting from an old scar in the posterior part of the heart.* Ordinarily that produces sudden death, but I understand that occasionally there can be a slow leak. I simply mention it as a possibility, and I do not see how one can rule it in or out.

I also mention the possibility that mural thrombi were thrown off to the cerebral hemispheres and possibly to the mesentery, which would explain the positive Babinski, the increasing disorientation and the tenderness in the left lower quadrant of the abdomen.

DR. WHITE: It is quite possible that this final illness started with myocardial infarction. The symptomatology strongly suggests this, but I have never seen a death from myocardial infarction — and heart failure — with such a high temperature due to myocardial infarction alone. There was one change in the precordial leads† that I did not emphasize earlier, as I probably should have done,

*Later comment by Dr. White. I take issue with the statement by Dr. Harwood that the heart occasionally ruptures through an old scar. Rupture of the heart may occur through a fresh myocardial infarct, almost always within the first ten days or two weeks, but not through an old, healed and tough scar, even when there is a fairly well marked cardiac aneurysm of long standing. Two recent papers emphasize this point.^{10, 11} In a series of 270 cases of myocardial infarction found among nearly 3000 autopsies at the Massachusetts General Hospital from 1933 through 1940, there were included 165 cases of old infarction and 105 cases of fresh infarction. There were 10 cases of cardiac rupture in the whole series, but all were found among the cases with acute infarction. In the second paper, 47 cases of myocardial infarction were found in 115 consecutive autopsies carried out in patients in mental institutions in Massachusetts. Twenty-five of these cases showed old infarcts, and in none of these cases was there cardiac rupture, but among the 22 cases of recent infarction there were 16 with rupture of the heart. The difference between the incidences in the two series, which were 10 per cent and 73 per cent, respectively, was doubtless due to the fact that in the former there was as a rule, adequate rest therapy during the process of healing, whereas in the latter there was little or none at all.

†During the last few years it has become customary at the Massachusetts General Hospital to take multiple precordial leads in any important or doubtful case, instead of the limb leads alone or the limb leads and lead 4, which is the routine apical precordial lead. On rare occasions all six precordial leads, extending from C₁ (at the right of the sternum in the fourth interspace) to C₆ (the midaxillary line), are taken (see below). Generally, however, in the appropriate cases, as in the case cited here, the three routine precordial leads are taken that have been found to be the most helpful, namely, C₁ (with the electrode in the fourth interspace just to the left of the sternum), C₄ (with the electrode at the intersection of the midclavicular line and a line drawn from the C₂ point to the cardiac apex) and C₅ (in the anterior axillary line at the intersection of the horizontal line from the cardiac apex). These have been found, in the main, to be by far the most useful, and they are relatively simple to take. They demonstrate most of the changes underlying the lead points that concern the right ventricle and the anterior and lateral walls of the left ventricle. Lesions of the posterior wall of the left ventricle are not adequately shown by these lead points or by any others, except an esophageal lead.

In the case under discussion, Lead C₃ would probably have shown the greatest change, since it overlies the region of the septum. The letter C designates chest, and the letter F, which is added in the case discussion above, refers to foot and indicates that the left leg is the site of the indifferent lead point. If the right arm is used in the precordial leads, one speaks of CR, and if the left arm is used, one speaks of CL. On occasion Wilson's lead-point, off the body altogether but connecting all three extremities and called V, has been used as the indifferent point for the precordial leads. It (CV) gives the balance or average of the other three (CF, CR and CL).

and that, in prominent form, was seen in the electrocardiogram at the last admission (Fig. 5), namely deep Q waves in Leads CF₄ and CF₅. This may mean a new acute myocardial infarction, but my experience has not been sufficient in this particular for me to be absolutely sure of its presence or of its location.

CLINICAL DIAGNOSES

Coronary heart disease.
Cardiac failure.
Bronchopneumonia.

DR. HARWOOD'S DIAGNOSES

Coronary heart disease.
Cardiac failure.
Bronchopneumonia.
Pulmonary infarction?
Myocardial infarction, recent?

ANATOMICAL DIAGNOSES

Coronary thrombosis, old and recent.
Myocardial infarcts, old: left ventricle, anterior and posterior.
Myocardial infarct, recent, septal: left and right ventricles.
Mural thrombi, left and right ventricles.
Pulmonary infarcts.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The autopsy showed an enlarged heart, weighing 500 gm. There was an old anterior myocardial infarct, which was completely healed, and a posterior infarct, which was also healed. The coronary arteries showed old occlusions. There was, however, a recent occlusion in the descending branch of the left coronary artery, 2.5 cm. from its origin, as well as a large recent septal infarct involving both the left and the right ventricle, a most unusual occurrence. There were mural thrombi on both sides of the septum, those on the right apparently accounting for four large pulmonary infarcts in the right lower, right upper and left lower lobes. This is one of the few cases in which we can be fairly sure that the emboli arose from the right side of the heart, because careful examination of the leg veins revealed no thrombosis. Usually, even in the presence of mural thrombi in the right heart, we believe that such emboli come from the deep veins in the legs.

DR. WHITE: The chief clue in the electrocardiogram to the septal infarct was not in the limb leads but evidently comprised the deep Q waves in Leads CF₄ and CF₅; this finding was distinctly abnormal and had not been present before.

DR. CASTLEMAN: Because the current use of precordial leads in electrocardiography is not too well known, I have asked Dr. White to present a brief review of this subject.

DECELERATION IN MEDICAL EDUCATION

SINCE September, 1941, the medical schools of the United States, by operating on a nine-month schedule, have done their best to meet the dire national need that became clear so suddenly after the attack at Pearl Harbor. The same motivation brought about a similar acceleration in the educational programs of our hospitals, where the 9-9-9 plan of rotating internships locked into the medical-school schedules, and of our colleges and even high schools, where premedical courses were given. There are now two indications that the pressure on this educational system may be reduced: the Army has altered its contract with the medical schools in such a way that, until further notice, it

will supply only 28 instead of 55 per cent of the matriculants, and the schools themselves are widely adopting the return to an annual period for the matriculation of future classes.

These moves on the part of the Army and of the medical schools call for rather prompt adjustments if future difficulties are to be avoided. They are not exactly movements in the same direction: the Army has reduced the number of its trainees but still calls for their continuous training and the medical schools have reduced the frequency of entering classes but are not yet in a position to return to a twelve-month basis. Unless the return to annual admission and a full-year course are made simultaneously and at the time — June — when courses formerly terminated, two things are bound to occur: first, for each year that the nine-month curriculum is retained, there will eventually be a delay of three months between medical-school graduations, with a maximum of a year, and second, when the twelve-month curriculum is resumed, the teaching schedules for three years will be chaotic. This brings up for immediate discussion, and for reasonably prompt decision, the question whether a return to the prewar timing of the curriculum is desirable.

This question has several phases. For the students at the top of the academic ladder, acceleration could be continued with profit and ease. These students can acquire in three years, as well as in four, the knowledge demanded, but there are not enough of them to supply the medical needs of the country — even in peacetime. The students at the bottom of the class in scholastic performance are definitely unable to complete the work satisfactorily in three calendar years, although many of them can do so in three and a half or four years. Many of these stable, hard-working students, who can do the work only if they are not hurried, have the attributes of character and personality that enhance their potential usefulness as physicians, and it is altogether proper that such persons be accorded some elasticity and consideration in the planning of the medical curriculum. The great majority of the students, however, stand in between these two ends of the academic ladder: they are the common denominators, they set the pace that the

occasions when a connection with the right arm or the left arm will be more useful. There is a scheme by which one can pick out the preferable lead, but it is complicated and for routine use during the past two years we have been using Leads CF_2 , CF_4 , and CF_6 .

FIGURE 6. Normal Electrocardiogram.

Normally, in Lead CF_2 (Fig. 6), there tend to be a small R, a deep S and an upright T, which, however, may be fairly low. The P wave is unimportant, since it may be upright, inverted or diphasic. In Lead CF_4 , R and S are frequently equal and there is a fair excursion of each. T is normally upright. In Lead CF_6 , R becomes higher and S shorter in the average normal and T continues to be upright but is lower. It is only in Lead C_1 that T may be inverted normally in the adult; in young children one may find that the normal precordial T wave is inverted.

MISCELLANY

MILITARY AWARD TO DR. LYONS

Major Champ Lyons, M.C., A.U.S., associate in surgery and instructor in bacteriology and immunology, Harvard Medical School, and assistant surgeon, Massachusetts General Hospital (on leave of absence), has recently been awarded the Legion of Merit because, according to his citation, "he initiated and guided the methods by which the new and potent agent penicillin has been utilized in the treatment of the seriously wounded." His citation continues: "From the most forward mobile hospitals of Italy to the large general hospitals of the Interior, he personally operated upon and studied the treatment of the wounded, instructing his seniors and subordinates alike in a change of surgical procedures which is productive of better results. Lives and limbs of soldiers have been saved, and the disability and deformity of wounds materially reduced. His professional judgment, combining a basic knowledge of the science of bacteriology with skill and experience in practical surgery, has cast new light on the age-old problem of wound surgery. At no time has he spared himself mentally or physically, and the example he has set is an inspiration to all surgeons in the service."

MILITARY AWARD TO DR. MOORE

Major Merrill Moore, M.C., A.U.S., former associate in psychiatry at the Harvard Medical School and the Boston City Hospital, has been awarded the Bronze Star Medal by Major General O. W. Griswold, commanding officer of the Fourteenth Army Corps. This award made by direction of the President, reads: "For meritorious achievement in connection with military operations against the enemy in the South West Pacific."

In recommending Major Moore for this citation, his commanding officer said specifically:

Your service at this base has been of the greatest benefit to the Government and to our war effort. Facing an immense problem, in your energetic and ingenious manner, you rapidly reduced the obstacle of psychoneurosis and related disorders in this area. As the only psychiatrist at that time, you immediately set about your assigned tasks with complete disregard for personal comfort and safety in your effort to solve existing difficulties. In addition to your regular hospital duties you devoted your personal leisure to consultations and lectures to all unit officers in this organization, often flying long distances to do so, so that they could understand and properly assist soldiers with emotional disturbances.

Of the large number of cases called to your attention by line officers or referred to you for diagnosis and treatment by medical officers, a remarkably high percentage were returned promptly to effective duty and the majority of the remainder were returned shortly thereafter. In doing this you were always efficient, sympathetic, reasonable and constructive.

Your performance of duty has been exceptionally meritorious. You have been a decided influence on the morale of our forces and an inspiration to the men with whom you have worked. You have strengthened co-operation and you have established confidence among officers and enlisted men as to the effectiveness of preventive psychiatry in the field as well as the value of mental hygiene for combat troops. Your actions contributed materially to the success of our combat operations.

NOTE

The following appointments to the teaching staff of Harvard Medical School have recently been announced: James Blanding Arey, of Minneapolis, Minnesota (S.B. University of Minnesota 1935, M.B. 1937, M.D. 1938 and S.M. 1940), instructor in pathology; Richard Colbert Cecil of Richmond, Virginia (A.B. Emory and Henry College 1925, M.D. Medical College of Virginia 1932), assistant in medicine; George Constantin Cotzias, of Canaan, Greece, now working at the Massachusetts General Hospital, Boston (M.D. Harvard University 1943), assistant in neurology; Peter Hugh Forsham, of New York City (B.A. University of Cambridge 1937, M.A. University of Cambridge 1941, M.D. Harvard University 1943), research fellow in medicine; Lee Nathaniel Foster, of Oak Park, Illinois (S.B. Northwestern University 1938, M.B. 1940, M.D. 1942), assistant in pathology; George Erwin Gutmann, of Chapel Hill, North Carolina (M.D. University of Louisville 1943), assistant in pathology; David Milford Hume, of Muskegon, Michigan (S.B. Harvard University 1940, M.D. University of Chicago 1943), assistant in surgery; Edith Meyer, of Jamaica Plain (Ph.D. University of Leipzig 1933), research fellow in pediatrics; Robert Durant Ray, of Berkeley, California (A.B. University of California 1936, A.M. 1938, M.D. Harvard University 1943), assistant in orthopedic surgery; Eli Robins, of Rosenberg, Texas (A.B. Rice Institute 1940, M.D. Harvard University 1943), assistant in psychiatry; Daniel Sciarra, of Paterson, New Jersey (A.B. Harvard University 1940, M.D. 1943), assistant in neurology; Paul John Votta, of Providence, Rhode Island (A.B. Brown University 1936, M.D. Boston University 1941), assistant in roentgenology; and Philip Hulet Walker, of Minneapolis, Minnesota (S.B. Harvard University 1939, M.D. 1943), assistant in surgery.

BOOK REVIEWS

An Atlas of Anatomy. Vol. 1. Upper limb, abdomen, perineum, pelvis and lower limb. By J. C. Boileau Grant, M.C., M.B. Ch.B., F.R.C.S. (Edin.). 4^o, cloth, 214 pp., with 227 illustrations. Baltimore: Williams and Wilkins Company, 1943. \$5.00.

Those familiar with the author's *Method of Anatomy* (Baltimore: Williams and Wilkins Company, 1940) will not be surprised that this first volume of an atlas of anatomy, devoted to the upper limb, abdomen, perineum, pelvis and lower limb, is characterized by originality of approach and treatment and by perfection of technic. The 227 illustrations, of which nearly half are in two or more colors, are made from enlarged photographic positives of actual dissections, traced and then worked up by a competent artist. They are unusually lucid and true, and free from the confusion of too much detail. The labeling of structures is clear; the text intentionally slight. It is intended that the student should use Dr. Grant's *Handbook for Dissectors* and refer to the *Method of Anatomy* mentioned above for description and comment. When the second volume of the atlas shall be issued, this group of books may be heartily commended to student and practitioner alike.

An Introduction to Group Therapy. By S. R. Slavson. 8^o, cloth, 352 pp. New York: The Commonwealth Fund, 1943. \$2.00.

In the author's words, this volume "deals with a method of psychotherapy employed at the Jewish Board of Guardians of New York since 1934 and known as Group Therapy." The board serves underprivileged city children, boys and girls, who present "problems of personality" of the sort that "may manifest themselves in the form of delinquent or neurotic behavior." Service is rendered to boys and girls up to the age of eighteen.

Among these children, the majority of those who are selected for group therapy are under fourteen and apparently none are under eight years of age. Each therapeutic group consists, ideally, of five to eight children, who meet periodically with an older person known technically as the "group therapist." By their members the groups are called "clubs," and this word adequately suggests the spirit in which the meetings are conducted.

The book offers a comprehensive and detailed exposition of the practical and executive problems presented by such therapy. Emphasis is placed on the close and successful integration of group therapy with other social-service activities and with individual psychotherapy, including even individual child analysis. The presentation contains many excellent case histories and many vivid play-by-play accounts of what has occurred in specific group meetings.

The theoretical point of view that synthesizes and directs this wealth of otherwise probably bewildering and inchoate details and activities appears to be strongly and even predominantly psychoanalytic. This is apparent not only in the general orientation of the book but also in the use and even definition of specific terms. Thus one meets repeatedly the words "super-ego," "transference" and, less exclusively psychoanalytic, "ego," and one reads that "the chief charac-

others find too slow or too fast, and they determine and maintain the standard at which medical education should be conducted. They have been hard pressed by the accelerated curriculum, but they have risen to the occasion and are responsible for whatever success has attended the project.

But there is a time factor in the educational process for which even the stimulus of war cannot compensate. The physicist, the chemist, the physiologist, the pathologist, the clinician, all take account of time in their scientific and practical calculations. So the educator might devise some such formula as $(c + r + e)t$ to designate the quality of his product, c being the intellectual capacity of the student, r the resources of the school attended, e the effort devoted to the educational process by both the student and the faculty, and t the time during which these processes are in operation. Whatever the formula or the philosophy, time is an inevitable element.

The facts that formerly most medical students devoted some — and a few, all — of their summer vacations to medical pursuits, that the members of the faculties, because of diminishing numbers, have had to give even more time to teaching than that demanded by the nine-month year and that a nine-month internship does not meet the minimum requirements mean that the quality of medical education, other things being equal, must have deteriorated during the wartime acceleration of the curriculum. It was an emergency device, — “any port in a storm,” — but it now appears that the storm has passed sufficiently for us to clear our decks again and to make our ship as stout and as seaworthy as possible. We are now planning to train the doctors of 1949 and later.

Are we to train them at the highest possible level and to meet the national and international responsibilities that we are now assuming? Before this question can be answered the time elements involved in the accelerated programs of our medical schools must be thoughtfully scanned by the medical, military and educational authorities of the Nation. The simplest method of deceleration would be to return to the annual type of curriculum and simultaneously to extend the 9-9-9 into a 12-12-12 plan for hospital internship. In the natural course

of events this would bring about a gradual, not a sudden, return toward normal. If these changes were to be made effective as of June, 1945, the future classes to graduate from our medical schools would have the following medical-school increments, including vacations: Class of 1945, thirty-six months; Class of 1946, thirty-nine; Class of 1947, forty-two; and Class of 1948, forty-five. Furthermore, each graduate would have at least a twelve-month internship.

Continuation of the nine-month curriculum beyond June, 1945, can be justified only by two considerations: first, that there are values in the accelerated program that should be projected into peacetime and, second, that the national emergency is still acute enough to sacrifice quality for quantity in medical-school output in 1948 and 1949. Furthermore, if the latter consideration does hold, it seems likely that both the Army and the country in general would be benefited if the required number of physicians were obtained by increasing the percentage of Army matriculants rather than by retaining the accelerated schedule.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

DION — Thomas J. Dion, M.D., of Quincy, died November 27. He was in his seventy-seventh year.

Dr. Dion received his degree from Laval University Medical Faculty, Montreal, in 1891. He was the oldest member of the Quincy City Hospital staff and had served as health commissioner and city physician in Quincy. He was a member of the American Medical Association.

His widow and a son survive.

O'NEIL — Richard F. O'Neil, M.D., of Boston, died November 30. He was in his seventy-first year.

Dr. O'Neil received his degree from Harvard Medical School in 1897. During World War I, he was commissioned a captain in the Medical Corps, serving as assistant to the surgeon-in-chief of the Department of Urology at Base Hospital No. 6 in France. He was promoted to major in 1918, and honorably discharged the following year. For several years he was private assistant to the late Dr. William M. Conant, outpatient surgeon at Carney Hospital and visiting surgeon at St. Elizabeth's Hospital. In 1911 he was appointed genitourinary surgeon in the Out Patient Department at the Massachusetts General Hospital. He was named visiting surgeon of the Genitourinary Service in 1915, and became chief of the service in 1917. He served as associate urologist at the Massachusetts General Hospital until 1934, when he was appointed to the board of consultation after reaching retirement age. He was well known at Harvard Medical School, where he was a member of the teaching staff. He was a member of the Boston and New England surgical societies and the American Medical Association and a fellow of the American College of Surgeons. He was a member of the American Urological Association, of which he was president from 1927 to 1928, as well as of the New England Section of the American Urological Association and the American Association of Genitourinary Surgeons, both of which he had served as president and secretary.

His widow and a son survive.

THE NEW ENGLAND JOURNAL OF MEDICINE

Number 25

Since the book covers the major research work done on the subject during the past ten years, it should be of considerable value to research workers.

Aesculapius in Latin America. By Aristides A. Moll, Ph.D., secretary-editor of the Pan-American Sanitary Bureau, Washington, D.C., and consultant in tropical medicine to the Secre-

teristic of the therapy group is its similarity to the family" and that the group therapist's, much like the psychoanalyst's, "chief function is to be a *neutral* person so that each . . . member of the group projects on the therapist his unconscious attitude toward adults."

On Growth and Form. By Sir D'Arcy Wentworth Thompson, 8°, cloth, 1116 pp., with 555 illustrations and frontispiece. New York: The MacMillan Company, 1943. \$12.50.

This famous and monumental monograph, written during World War I and first published in 1917, has been out of print and extremely scarce for the past twenty years. The present edition has been revised and enlarged by its distinguished author as a *solacium ac perjugium* when active service was debarring him by his years. Much new material has been added. The chapter on rate of growth is double its original length; and the subjects of the bee's cell, the radiolarian skeleton, the mechanical construction of a bird, and Galileo's principle of similitude have been much extended. So unbounded is the writer's range of knowledge that scarcely any subject in biology is untouched. There is discussion, for example, of the fascinating problem of the left-handed snail shell and of the tetrakaidekahedral shape of cells in cell-aggregates, first noted by Joseph Plateau and Lord Kelvin and so beautifully demonstrated in this country by Dr. F. T. Lewis, of the Harvard Medical School.

Sir D'Arcy Thompson is a man of science who writes like a novelist; all the charms and merits of literary excellence and style are his. Moreover, so vast is his erudition that his volume is a treasury of apposite classic allusion and universal scientific reference. It is a work of perfect, total and utter scholarship, wherein the author, like Henri Fabre, the old man eloquent to whom he refers, "in his all but secular life has tasted of the first fruits of immortality."

Civilization and Disease. By Henry E. Sigerist, M.D., D. Litt., LL.D., 8°, cloth, 255 pp., with 52 illustrations. Ithaca, New York: Cornell University Press, 1943. \$3.75.

The part played by disease in determining the progress and even the form of civilization is the fascinating subject that Dr. Sigerist discussed in the Messenger Lectures for 1940 and that he has further expanded in this delightful volume. Civilization is first presented as a factor in the genesis of disease, and in subsequent chapters, the relation of disease to economics, social life, law, history, religion, philosophy, science, literature and art is studied. Not less valuable than the factual matter are the glimpses that the reader gets of the author's philosophic assay of conditions and factors that, through the ages, have brought the world to its present pass, and he will be comforted by a final declaration: "The more I study history, the more faith I have in the future of mankind. . . . While we are struggling, the foundations are being laid for a new and better civilization."

The volume is excellently turned out, and is embellished by many beautiful reproductions of treasures from the world's museums. An excellent index gives quick guidance, whether one's interest be in "worms" or "Hitlerism."

Many a reader of this volume will find difficulty in laying it down unfinished, and will long for the leisure to browse among the sources of the allusions and references that are so lavishly spread before him.

Female Endocrinology. By Jacob Hoffman, M.D., 8°, cloth, 780 pp., with 180 illustrations. Philadelphia: W. B. Saunders Company, 1944. \$10.00.

This book is an able exposition of the accumulated knowledge of endocrinology as it pertains to women. The book is really more than a review of female endocrinology, since it contains chapters on all the endocrine glands, in their relation not only to female physiology and pathology but also to general body physiology. This constitutes the reviewer's main criticism. To explain the mechanism and workings of all parts of the body a volume many times larger than this is needed, and in a book dealing with female endocrinology the pertinent relation of the nongenital glands to the genital glands should be sufficient. As a reference book it is good, since nearly all the important work of the last fifteen years has been included. Like all books on such a rapidly changing subject it cannot keep up with the times.

The careful explanation and the actual description of the technics for hormone determinations will be valuable to all workers in the field, especially those in laboratories in which such tests have not been performed. In the opinion of the reviewer this book is an excellent and able work on female endocrinology, but it should always be recognized that such a book is far from definitive.

Clinical Lectures on the Gallbladder and Bile Ducts. By Samuel Weiss, M.D., 8°, cloth, 504 pp., with 125 illustrations and 21 tables. Chicago: The Year Book Publishers, Incorporated, 1944. \$5.50.

This is a nicely dressed book, well printed and well illustrated. It discusses diseases of the gall bladder and bile ducts in a series of twenty-nine clinical lectures. The method of approach makes for easy reading, introducing a certain degree of informality that is pleasant. At the end of each lecture is a bibliography, placing at the reader's disposal a great deal of pertinent modern literature. On the whole the volume is by no means exceptional, but on the other hand covers its subject adequately and in a practical manner that may appeal to many readers.

Handbook for the Medical Secretary. By Miriam Bredow. First edition. 8°, cloth, 253 pp., with 18 illustrations. New York: McGraw-Hill Book Company, Incorporated, 1943. \$2.25.

Miss Bredow has produced an excellent handbook to be used as a guide to the conduct of a medical secretary or assistant. It deals with general information peculiar to the physician's office: patients, their records, filing, handling of appointments, accounts, correspondence and office procedure. The author also has included a brief description of various specialties of medicine, suggestions concerning the preparation of scientific manuscripts and a summary of the relation between the doctor and the law. A glossary of 2000 medical terms appears at the end.

If used with intelligent application, not as an irrevocable authority, this book will fill a much needed place as a textbook for the teacher and student of medical secretarialship as well as a reference book for those already holding such positions. It would be impossible for one small volume to be all inclusive since each chapter could overflow easily into a separate monograph and there is no vocation where such a variety of methods and experiences may be encountered as that of medical secretary.

Osler's Principles and Practice of Medicine. By Henry A. Christian, A.M., M.D., LL.D., Sc.D. (hon.), Hon. F.R.C.P. (hon., Can.). Fifteenth edition. 8°, cloth, 1498 pp. New York: D. Appleton-Century Company, Incorporated, 1944. \$9.50.

The fifteenth edition of *Osler's Principles and Practice of Medicine* is off the press. In appearance and general make-up it follows previous models; the chief difference is that it is more Christian and less Osler than heretofore.

When medical textbooks are discussed, two divergent viewpoints are apparent: one claims that no single person can know enough of medicine to compose a useful book that is properly inclusive, and the other that one writer of wisdom and broad experience, particularly if he happens to be an assiduous student of medicine with an adroit pen, can produce a volume that is fully as informative, more evenly written and better balanced in use of space or material than any developed through polyandry.

This reviewer confesses that he belongs to the latter school. Thus he has enjoyed succeeding editions of *Osler*, — in part because of the very fact that they were written by one author, — always finding each one refreshing, agreeable to study and serviceable. The fifteenth is no disappointment.

Those who have been brought up on *Osler* will appreciate the ease with which the book can be read — a tribute to Dr. Christian's ability to carry on the Oslerian tradition as a writer; the references to pertinent literature, which come at the end of each section and are amazingly up to date — a tribute to Dr. Christian's ability to extract the meat from periodical literature as it accumulates; and the index at the end by which any topic from abasia to zinc poisoning can be located without difficulty — a tribute to good bookmaking.

Number 25

THE USE OF SULFADIAZINE AS A PROPHYLACTIC AGAINST RESPIRATORY DISEASE*

CAPTAIN RICHARD G. HODGES, M.C., A.U.S.

DURING the winter season of 1942-1943, an Army Air Force technical school, located in the midwestern part of the country, experienced a severe epidemic respiratory disease. Waves of streptococcal sore throat and pneumococcal pneumonia struck the post in mid-February, 1943, and these diseases persisted at high levels until the end of May. During January, 1944, the rate for streptococcal sore throat again rose to a high level, reaching 6.0 admissions per 1000 men a week; at the same time, the incidence of lobar pneumonia rose to 5.6 admissions per 1000 men a week. It appeared that the epidemics of the previous winter were about to be repeated, and the decision was made to try the prophylactic effect of sulfadiazine.

METHOD OF INVESTIGATION

The technical school furnished an ideal population for investigation. The school is divided into two teaching shifts, each composed of approximately 1000 men. The general environment, the living conditions, the duties and even the recreations of the two groups are identical. The shifts are on different time schedules, so that mixing between the two is minimal. During the period of observation, the percentage distribution according to length of service, that according to duration of stay on the post and that according to age were calculated for each of the groups; no significant differences were found. The inflow of new troops into the groups was determined and was also found to be closely similar for the two. Finally, respiratory disease had been carefully followed in the school for many months and at all times the component units had shown a closely similar trend in disease rates.

The sulfadiazine pills were distributed by the squadron command. Each man admitted to the hospital was asked whether he had taken his pills, and numerous statements were obtained concerning how consistently the medication was being taken. It is estimated that for a given day 15 per cent of the men failed to take pills owing to having

days off, being on work details or failing to cooperate. In this respect, no single squadron appeared to be worse than the others. During a three-day period following each administration of the drug, corrections were made for men admitted to the hospital who had failed to take the pills when they were supposed to, 28 such patients being dropped from the series under study.

Hospital admissions were used to score the results. Attendance at sick call was not tabulated, but estimates of its volume were obtained from dispensary officers and in all instances paralleled the experience with hospital admissions. Each patient admitted was followed on the ward until the diagnosis was established, and his chart was checked following discharge.

The cases were classified as follicular tonsillitis, lobar pneumonia, atypical pneumonia and ordinary respiratory disease. The diagnosis of follicular tonsillitis was made in the presence of pharyngeal edema with exudate. Thirty per cent of the cases were cultured. Of these, 92 per cent were positive for beta-hemolytic streptococci, 3 per cent were positive for pneumococci, and 5 per cent were negative. From this it was concluded that follicular tonsillitis was an indication of streptococcal infection. Lobar pneumonia was identified by its clinical picture and by x-ray examination. Pneumococci were typed from 75 per cent of the cases. Atypical pneumonia was distinguished by its clinical picture. The remaining cases, classed as ordinary respiratory disease, included rhinitis, pharyngitis, laryngitis and acute bronchitis.

RESULTS

Effect on total respiratory disease. Figure 1 shows the response of admissions for all types of respiratory disease to the administration of sulfadiazine. On February 2, 3 and 4, 1944, members of Teaching Shift A received 2 gm. a day. The admission rate of the group promptly fell and for ten days remained between one third and one half that of the control group. On February 18 and 19, members of Teaching Shift B received 2 gm. a day. The

*From the Army Air Force Rheumatic Fever Control Program

teristic of the therapy group is its similarity to the family" and that the group therapist's, much like the psychoanalyst's, "chief function is to be a neutral person so that each . . . member of the group projects on the therapist his unconscious attitude toward adults."

On Growth and Form. By Sir D'Arcy Wentworth. Principally 8°, cloth, 1116 pp., with 555 illustrations scattered throughout. New York: The MacMillan Company, 1944. Appended to the text—

This famous and monumental monograph in Latin America and World War I and first published (1492 to 1943). A bibliography and extremely scarce indices of names and subjects present edition has been is an essential text for all libraries, distinguished author as, and for all historians.

service was debarred. *Methods of the United States Army.* Edited by original les. Simmons, M.D., Ph.D., D.P.H., Sc.D. (hon.), larian,adier general, M.C., U.S.A., chief of the Preventive Medical Service, Office of the Surgeon General, lecturer, Department of Preventive Medicine, Johns Hopkins University School of Medicine, lecturer in public health, Yale University School of Medicine, professorial lecturer in preventive medicine, George Washington University Medical School, and lecturer in tropical medicine, Army Medical School; and Cleon J. Gentzkow, M.D., Ph.D., colonel, M.C., U.S.A., and commanding officer, Deshon General Hospital, Butler, Pennsylvania. Fifth edition. 8°, cloth. 823 pp., with 103 engravings and 8 color plates, Philadelphia: Lea and Febiger, 1944, \$7.50.

This composite work was first published as *Medical War Manual No. 6* and was written during World War I by officers of the United States Army. Since that time the manual has passed through four editions and has been enlarged at each appearance. This fifth edition has been revised throughout to bring it thoroughly up to date; many sections have been completely rewritten.

Guiding the Normal Child. By Agatha H. Bowley, Ph.D. With a foreword by D. R. MacCalman, M.D., Crombie-Ross Lecturer in Psychopathology, University of Aberdeen. 8°, cloth, 174 pp., New York: Philosophical Library, 1943, \$3.00.

This small book describes the normal growth and development of children from birth to adolescence; it is of a popular character and designed for all persons interested in child guidance and the proper growth of children, and should be of interest to physicians. Emphasis is placed on the psychological aspects and on the development of personality. The manual is divided into four periods of a child's life: infancy, preschool period, the middle years of childhood and adolescence. A chapter on children and the war concludes the volume.

The Letters of Doctor George Cheyne to Samuel Richardson (1733-1743). Edited, with an introduction, by Charles F. Mullett, Ph.D., professor of history, University of Missouri. Vol. XVIII. The University of Missouri studies: No. 1. 4°, paper, 137 pp., with 4 illustrations, and frontispiece. Columbia, Missouri University; University of Missouri, 1943.

This monograph reproduces eighty-seven letters written during the period 1733 to 1743 and copied into a notebook owned by Samuel Richardson and now in the University of Edinburgh library. The existence or whereabouts of the original letters are unknown. This work should be of interest to historians of medicine and should be added to history collections in medical libraries.

Rorschach's Test. Volume I: Basic Processes. By Samuel J. Beck, Ph.D., head of the Psychology Laboratory, Department of Neuropsychiatry, Michael Reese Hospital, Chicago, and associate professor of psychology, Northwestern University. With a foreword by Willard L. Valentine, Ph.D., head of the Department of Psychology, Northwestern University. 8°, cloth, 223 pp. New York: Grune and Stratton, 1944. \$3.50.

The intent in the present volume is to demonstrate the processes used in evaluating responses to the Rorschach test. The sole purpose is to provide students with a moderately steady frame of reference, with the hope that given such a manual of constant usage it will be possible to work with the test as a stable instrument.

Medicine Annual—1943. 8°, cloth, 659 pp., with 100 illustrations. Minneapolis: Modern Medicine, 1944.

This is a collection of abstracts in all fields of medicine and surgery, which are brought together for convenient reference. All were originally published in the periodical, *Modern Medicine*. They are grouped by subject. The latest developments in the use of penicillin, sulfonamides, hormones and vitamins are discussed. The newer procedures in the diagnosis and treatment of cardiac and gastrointestinal disorders are considered, as well as techniques in every phase of surgery and orthopedics. There is a special division on military medicine and surgery in its various aspects, comprising thirty-two articles. The abstracts are short and well condensed, and provide a review of practical medicine and surgery as seen by the specialist in 1943. This manual should prove useful for ready reference purposes and should be in all medical libraries.

The Principles and Practice of Medicine, Originally written by Sir William Osler. By Henry A. Christian, M.D., LL.D., Sc.D. (hon.), F.R.C.P. (hon.) (Can.), clinical professor of medicine, Tufts College Medical School, and visiting physician, Beth Israel Hospital, Boston. Fifteenth edition. 8°, cloth, 1498 pp. New York: D. Appleton-Century Company, Incorporated, 1944.

This edition has been revised to place in the hands of the medical practitioner and Army and Navy personnel the most recent information brought to light since the publication of the preceding edition in 1942. Special emphasis is given to infectious and venereal diseases, tropical medicine and food deficiency disorders.

Textbook of General Surgery. By Warren H. Cole, M.D., professor and head of the Department of Surgery, University of Illinois College of Medicine, and director of Surgical Service, Illinois Research and Educational Hospitals, Chicago; and Robert Elman, M.D., associate professor of clinical surgery, Washington University School of Medicine, assistant surgeon, Barnes Hospital, associate surgeon, St. Louis Children's Hospital, and director of Surgical Service, H. G. Phillips Hospital, St. Louis. Fourth edition, 8°, cloth, 1118 pp., with 559 illustrations. New York: D. Appleton-Century Company, Incorporated, 1944. \$9.50.

The first edition of this book was published in 1936 and it was thoroughly revised in 1941. This fourth edition has been brought up to date by the inclusion of new material throughout the text. New pages have been added to include more data on fluid and electrolyte balance of amino-acid therapy, hypoproteinemia, transfusion, chemotherapy and appendicitis. Increased emphasis has been placed on wounds, burns, surgical shock and other subjects related to war casualties. Despite the addition of new material the book has been kept the same size as the previous edition by the elimination of obsolescent material. A new chapter has been added, entitled "War and Catastrophe Surgery." Some of the illustrations have been improved and others have been replaced.

NOTICES

NEW ENGLAND OPHTHALMOLOGICAL SOCIETY

A meeting of the New England Ophthalmological Society will be held at the Massachusetts Eye and Ear Infirmary, 243 Charles Street, Boston, on Tuesday, December 19.

At 7:30 p.m. there will be a demonstration of clinical cases followed by the business meeting. Drs. David Cogan and Morton Grant will then speak on the topic "An Unusual Type of Keratitis Associated with Exposure to Butanol," and Dr. Theodore L. Terry on the subject "Pathology of Eyes following Maternal German Measles." These will be followed by a paper "The Myopia Paradox" by Dr. S. Judd Beach, including a discussion opened by Dr. Walter B. Lancaster.

SOUTH END MEDICAL CLUB

A regular meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, December 19, at twelve noon. Dr. E. Everett O'Neil will speak on the topic "The Treatment of Venous Thrombosis and Embolism." Dr. Samuel Grossman will preside.

Physicians are cordially invited to attend.

(Notices continued on page xix)

pneumococci. In the ten months preceding the experiment an average of 30 per cent of the pneumo-

FIGURE 3. The Effect of Sulfadiazine on the Incidence of Lobar Pneumonia.

The solid line represents Shift A, and the dotted line, Shift B.

cocci typed were found to be Type 2. During the period of observation, this proportion rose to ap-

proximately 50 per cent. Increases in the proportion of Type 2 pneumococci could not, however, be correlated with the individual administrations of the drug.

Effect on ordinary respiratory disease. As shown in Table 2, the admissions for ordinary respiratory disease were affected in a manner and degree quite similar to those for pneumococcal infection. It has been suspected for some time that a fair proportion of the cases with this diagnosis were in reality bacterial infections. Beta-hemolytic streptococci and epidemic types of pneumococci were isolated from a number of these patients. It is presumed that this is the explanation for the effect of sulfadiazine but extensive laboratory work would be necessary to prove this point.

Effect on atypical pneumonia. Throughout the period of observation, the incidence of primary atypical pneumonia was low, being almost exactly one third that of pneumococcal pneumonia. This corresponded to the relatively low rate for ordinary

respiratory disease, it being the experience at this post that an average of 1 case of atypical pneumonia is admitted for every 10 cases of ordinary respiratory disease. The cases of atypical pneumonia were too few for significant analysis.

Effect on acute rheumatic fever. The streptococcus epidemics of streptococcal infection in 1943 and 1944 are contrasted in Figure 4. In the 1943 season, approximately eight weeks after the sharp February rise acute rheumatic fever appeared in epidemic proportions. In spite of the extremely high rates of January and February, 1944, no such outbreak of rheumatic fever appeared. This is demonstrated in Table 3, in which weekly rheumatic fever rates for the two years are compared, using the onset of the streptococcus epidemics as starting points. It should be borne in mind that although the 1944 curve of streptococcal infection appears to be continuous, it was in reality sharply broken for each group by the use of sulfadiazine (Fig. 2). It is not

that sulfadiazine had a prophylactic effect on the development of acute rheumatic fever.

decrease in the admission rate was equally striking, but the duration of the effect was more transitory, lasting only four days. On March 7, the members of Teaching Shift B began to take 1 gm. of sulfadiazine a day. On March 8 and 9, and again on March 15 and 16, the members of Teaching Shift A received 2 gm. a day. Admissions from both groups fell sharply. The rate from Teaching Shift B remained low while the men were receiving the drug

Effect on pneumococcal infection. As was pointed out above, pneumococci were typed from 75 per cent of the patients with lobar pneumonia. Thus, the effect of sulfadiazine prophylaxis on lobar pneumonia admissions may be taken as a measure of its effect on pneumococcal infection. The effect of sulfadiazine prophylaxis is shown in Table 2 and Figure 3. The experimentation period is roughly divided into intervals of two weeks. In the periods follow-

FIGURE 1. *The Effect of Sulfadiazine on the Incidence of Total Respiratory Disease. The solid line represents Shift A, and the dotted line, Shift B.*

daily. The rate for Teaching Shift A rose moderately five days after the second weekly treatment.

Effect on streptococcal infection. As might be expected, the most striking results were obtained with streptococcal sore throat or follicular tonsillitis (Table 1 and Figure 2). It is apparent that adminis-

ing the administration of the drug, the average daily number of admissions from the treated group fell; in the periods when no drug was given, it rose. Considering that the treatment periods included in

tration of the drug reduced the incidence of this disease almost to zero.

Likewise, the response of scarlet fever to the medication (Table 2) was striking, the admissions dropping almost to zero.

FIGURE 2. *The Effect of Sulfadiazine on the Incidence of Streptococcal Sore Throat. The solid line represents Shift A, and the dotted line, Shift B.*

tervals when the rates were returning to pretreatment levels, the results appear to be significant. It is possible that part of this reduction was due to the control of upper respiratory disease, resulting in a lessened dissemination of pneumococci.

Sulfadiazine failed to produce any clear-cut change in the distribution pattern of the various types of

THE PREVENTION OF PULMONARY EMBOLISM*

CHARLES A. ROBINSON, M.D.†

BOSTON

EVERY adult person who is confined to bed with illness — whether operative, medical, obstetric or traumatic — is a potential candidate for a pulmonary embolus. There is scarcely a physician who has not witnessed the sudden death caused when an embolus is propelled into the pulmonary artery from an unrecognized source. In such grave crises one is compelled to stand helplessly by the bedside, administering drugs futilely and almost at random in an attempt to bring the heart beat, blood pressure and respiration back to normal. Yet if preliminary observations are made and routine measures are taken, a large percentage of these deaths can be avoided.

No one knows for certain how many deaths are attributable to pulmonary embolism, but the mortality can best be appreciated if one considers the statistics of the pathologist. Barnes¹ writes:

According to Belt, pulmonary embolism was the cause of death in 6.5 per cent of 567 consecutive cases in which necropsy was performed on adults. McCartney reviewed 14,419 cases in which necropsy was performed on persons of all ages. In 9615 of these cases the patients had been treated medically; in the remaining cases the patients had died after operation, accident or obstetric delivery. Pulmonary embolism accounted for 2.72 per cent of deaths in this series. Collins reported 2.07 per cent of deaths from pulmonary embolism of 10,940 consecutive cases in which necropsy was performed at the Los Angeles Hospital. Subject to whatever selectivity such a series of cases represent, one can estimate that 34,000 people die of pulmonary embolism yearly in the United States. If such a percentage of deaths from pulmonary embolism is applicable to the general population, and unless this expectancy can be modified, it may be assumed that more than 3,000,000 people now living in the United States will eventually die of pulmonary embolism.

Great confusion exists among physicians regarding inflammatory diseases that attack the veins of the leg. Although it is true that all these diseases may be the precursors of pulmonary embolism, two of them — namely, thrombophlebitis of varicose veins and phlegmasia alba dolens, generally known as "milk leg" — rarely give rise to fatal complications, because in these diseases the thrombus is firmly attached to the vein wall. It must be pointed out that thrombophlebitis of varicose veins is an ailment of the superficial venous circulation, and can be easily diagnosed and successfully treated by ligation and division of the great saphenous vein and all its tributaries at the fossa ovalis. The swelling and pain of phlegmasia alba dolens can be successfully treated by novocain block of the lumbar sympathetic ganglions.

The type of phlebitis known as "phlebothrombosis" is far more dangerous than either of the diseases mentioned, and carries a much higher mortality. It is this malignant complication of the deep veins of the lower leg that gives rise to the vast majority of pulmonary emboli. Here they originate, lurking in the retarded blood stream and waiting to detach themselves either in whole or in part from the venous intima. If such detachment occurs, the clot is borne along the ascending venous circulation into the right auricle, and thence into the pulmonary artery and lung. At this point, either the patient suffers nonfatal embolism that produces an infarct of the lung or, if the entire thrombus tears loose and is of sufficient caliber, the pulmonary artery is blocked and death is a matter of minutes or even seconds. This disease entity is generally unobserved by the physician, and it is his tardiness or failure in detecting it that often leads to the much-dreaded pulmonary embolus. The following case is typical.

CASE 1. A 50-year-old, married woman was operated on for a panhysterectomy. Her recovery was seemingly uneventful until the 12th postoperative day, when she complained to the resident surgeon of pains and soreness in the left groin. When I questioned the patient, she admitted that she had noticed the pain 3 days previously in the left calf, but had not told the resident surgeon about it because she feared she would not be allowed to sit up. In the same period, the temperature and pulse had shown an unexplained rise. It should be noted that 3 critical days had elapsed since the appearance of the first symptoms.

Physical examination showed definite tenderness in the muscles of the left calf, with moderate swelling of the leg and a strongly positive Homans's sign. (To test for the Homans's sign the Achilles tendon is put on stretch by forcefully flexing the foot; where the sign is present, this manipulation causes pain in the calf of the leg.) There were tenderness and swelling over the femoriliac region, and slight cyanosis of the foot on dependency. (These constitute the classic signs and symptoms of late phlebothrombosis.) The symptoms were so obvious that venograms were not necessary.

An operation was immediately performed. The left femoral vein was opened under local anesthesia and a thrombus 18 cm. long, whose proximal end was non-adherent to the femoral vein and floating in the venous circulation, was removed. The right femoral vein was also opened, but no thrombus was found. The patient became ambulatory within 24 hours and was discharged on the 6th postoperative day.

In this classic case of late phlebothrombosis, one hesitates to surmise what would have happened if the symptoms had not been recognized and traced to their deepest significance, for it is cases like this that so frequently cause fatal pulmonary embolism. Actually, there was laxness in the precautionary routine of daily examination of the legs for the very signs and symptoms that were belatedly discovered.

Judging from the above case, phlebothrombosis may be misconceived as a highly dramatic and

*Presented at the annual meeting of the Massachusetts Medical Society, Boston, May 24, 1944.

†Junior visiting surgeon, First Surgical Service, and chief of Varicose Vein Clinic, Carner Hospital.

Dosage. The least prolonged response to sulfadiazine was obtained by the administration on February 18 and 19 of 2 gm. a day to the members of Teaching Shift B. It is suspected that the shortness of this response may have been due to a heavy saturation of this group with streptococci during

nor was any depression of the blood-cell counts found. Patients with pneumococcal pneumonia who had received the drug prophylactically appeared to respond as well as ever to sulfadiazine.

SUMMARY AND CONCLUSIONS

During the month of January, 1944, hospital admissions for streptococcal and pneumococcal infections from an Army Air Force technical school rose abruptly and alarmingly. The experience of the preceding year suggested that serious and prolonged epidemics were beginning. The decision was made to try the prophylactic use of sulfadiazine, the organization of the school and the character of its component troops providing an ideal population for a controlled experiment.

Administrations of sulfadiazine were made throughout the months of February and March. In each instance the results appeared to be clear cut and beneficial. The most striking effect was on beta-hemolytic streptococcus infection. It appeared that streptococcal sore throat and scarlet fever could be reduced almost to zero. There was a less marked but still significant effect on pneumococcal infection. Sixteen weeks after the onset of the epidemic of streptococcal infection the incidence of acute rheumatic fever was well below the expected rate. Ordinary respiratory disease also showed a response to the drug. This is thought to be due to the fact that streptococci and pneumococci give a clinical picture indistinguishable from that of the common cold, although this concept remains to be proved.

A variety of dosages was tried. It is believed that the optimal dosage for a given group should be worked out individually.

No serious untoward reactions occurred.

TABLE 3. Comparisons of Admissions for Acute Rheumatic Fever in 1943 and 1944.

No. OF WEEKS AFTER ONSET OF STREPTO- COCCUS EPIDEMIC	1943		1944	
	NO. OF CASES	ADMISSION RATE	NO. OF CASES	ADMISSION RATE
1	0	0	3	0.34
2	1	0.07	2	0.22
3	2	0.15	2	0.21
4	1	0.08	2	0.22
5	3	0.23	3	0.33
6	2	0.15	4	0.43
7	10	0.78	0	0
8	6	0.46	5	0.51
9	12	0.90	2	0.20
10	12	0.92	5	0.30
11	5	0.38	2	0.20
12	15	1.19	3	0.30
13	10	0.76	1	0.10
14	5	0.38	2	0.18

16	10	0.76	3	0.25
17	6	0.46	2	0.16

the period February 2-16. The best response appeared to be from the prolonged daily administration of 1 gm. The data for March 7-19, however, indicate that there may be little to choose between this dosage and the administration of 2.0 gm. on two consecutive days once a week. It is believed that any given group represents a special problem in which a balance must be struck between economy in the use of the drug and an optimal therapeutic effect.

Untoward reactions. No serious reaction to the drug occurred during the period of observation. There were 2 moderately severe and several minor skin reactions. No renal symptoms were reported,

The literature clearly indicates that the maintenance of fluid balance is vitally important. This rationale is based on the fact that a dehydrated patient has a slower circulatory rate. It is imperative to keep a charted record of intake and output to maintain the fluid balance scientifically.

Since patients having varicose veins have been shown to be especially likely to develop superficial and deep phlebitis, it seems logical that if a patient has varicose veins they should be ligated, divided and injected before the fifth month of pregnancy, or prior to any elective operation. This comparatively simple treatment has been shown by many investigators to reduce the menace of pulmonary embolism. Warning must, however, be given that no varicose veins should be injected with a sclerosing solution without a preliminary ligation and division of the great saphenous vein. Failure to take this precaution has resulted in a number of deaths from pulmonary embolism.

Surgical trauma is a factor in causing phlebitis. Rough handling of tissues, leaning on the patient, especially over the femoroiliac region in abdominal operations, and poor approximation of tissues are possible contributory agents in failure to re-establish the normal venous return. For the same reason the holding of the legs is advisable in long gynecologic and obstetric operations are preferable to the use of stirrups. In addition, patients should also be out of bed and walking after a period of observation before the actual operation takes place. They should be made ambulatory by the third day after operation, especially elderly patients.

Many authorities, basing their conclusions on recent findings in biochemistry, look forward to the day when phlebitis will be prevented, or at least successfully treated, by the use of anticoagulant drugs. The medical literature is beginning to resound with claims made for heparin and dicoumarol,

both of which have the significant property of preventing the formation of blood clots. Barker, Allen and Waugh² report a series of 479 cases at the Mayo Clinic in which dicoumarol was used to increase the prothrombin time with a view to the prevention of pulmonary embolism. I have been unable to verify these results in my cases. There are so many contraindications to the use of this drug that it is perhaps unwise at the present time for the medical profession at large to employ it in the treatment of phlebothrombosis and thrombophlebitis. It apparently caused bleeding in ten per cent of the cases at the Mayo Clinic, and it cannot be safely used on patients suffering from blood dyscrasias, jaundice, hepatic disease and kidney complications. Heparin has the same end effects as does dicoumarol and is, in addition, much more expensive. The fact that it must be administered intravenously and that bidaily coagulation times must be obtained certainly does not enhance its attractiveness for general use at the present time.

* * *

Until such time as the anticoagulants have proved themselves to be safe and inexpensive drugs, the medical profession must depend on prophylactic measures, early diagnosis and surgery for the prevention of pulmonary embolism. This is a field in which the average physician, by simple routine expedients such as those described, followed by prompt utilization of surgery, can substantially reduce the mortality in cases of pulmonary embolism.

easily diagnosed condition. Actually, the usual picture is quite the opposite. The early symptoms are obscure, indefinite and frequently overlooked. A considerable degree of diagnostic skill, together with routine daily examination of the lower extremities, is imperative if pulmonary embolism is to be avoided.

The following case illustrates an undramatic but undoubted case of phlebothrombosis in which we were fortunate enough to make an early diagnosis.

CASE 2. A 31-year-old multipara entered the hospital in moderate labor after an uneventful prenatal course. There was no history of varicose veins or previous phlebitis. Nine hours later she was delivered of a normal baby girl by spontaneous delivery, with a first-degree perineal laceration. The post-partum course was uneventful. The temperature and pulse remained normal for 7 days. The usual routine examination of the legs had been made each day, with no positive findings. On the 7th day, there were an unexplained temperature of 99.2°F. and a pulse of 94, accompanied by slight pain in the left calf. On surgical consultation there was moderate tenderness over the left calf muscles and a mildly positive Homans's sign. There was no swelling in the leg or cyanosis of the foot on dependency. It was suspected, however, that the patient had an early phlebothrombosis, and this was confirmed by venograms. Opening the femoral vein of the left leg revealed no thrombosis, and the usual ligation and division were performed. The right femoral vein was also opened. The postoperative course was uneventful, and the patient was discharged in 6 days.

Provided that a clot existed in the calf, the question arises whether if no femoral exploration had been made the clot would have spontaneously disappeared or would have resulted in embolus. The answer is not known but it is certain that the symptoms disappeared after the operation and that the danger of pulmonary embolism from this site was eliminated.

A patient may survive the initial embolus, but statistics prove that a second or third usually results in death. Obviously these emboli ascend from a deep phlebothrombosis. If disaster is to be avoided, either they must be surgically removed or the vein must be ligated and divided above the offending thrombus. Sometimes to get above the clot it is necessary to ligate as high as the inferior vena cava.

Occasionally a pulmonary embolus produces an infarct of the lung even before phlebothrombosis is recognized. This is a difficult diagnosis, requiring the keenest perception on the part of the physician. The following case illustrates an infarct that had been treated as pneumonia.

CASE 3. A 40-year-old man was discharged to his home from another hospital after convalescing from a supposed right lobar pneumonia. Three days after discharge he experienced a sudden sharp pain in the left side of the chest and coughed up blood. His physician diagnosed this as pneumonia in the opposite lung and put him to bed. The next day the patient experienced a severe pain in the left thigh and calf, which lasted for 17 hours. An internist was consulted and made a diagnosis of a pulmonary infarct, on the basis of the left lung and the swelling and tenderness of the right leg, together with a positive Homans's sign. The patient was taken to the Carney Hospital, where I confirmed the diagnosis of ascending phlebothrombosis of the femoral vein.

At an emergency operation the right femoral vein was found to contain a thrombus, fairly adherent to the vein wall, which was removed by instruments and suction. The left femoral vein was clear but was surgically divided routinely. The postoperative course was uneventful. The patient was out of bed within 24 hours and was discharged on the 10th hospital day. On the day before discharge x-ray examination of both lungs was negative.

There can be no reasonable doubt that this patient had developed a phlebothrombosis while lying in bed during the original illness. The correct diagnosis was completely overlooked by the patient's physician but was fortunately recognized by the consultant, who was familiar with the signs and symptoms of phlebothrombosis. Delay in operating might have resulted in a fatal embolism. There must be no waiting period after a diagnosis of phlebothrombosis has been made.

Seventy-two operations for exploration and division of the femoral vein have been performed at the Carney Hospital in the last two years, all demonstrating three cardinal lessons. The first is that phlebothrombosis usually occurs when the patient is lying in bed with the venous circulation retarded and the tone of the muscles relaxed. The second is that the diagnosis is frequently overlooked when the physician fails to make a routine examination of the lower extremities — especially the calves — during his daily ward rounds and neglects to note any unexplained slight rises in temperature and pulse. The third is that if phlebothrombosis is diagnosed, there must be no waiting period before surgical exploration of the veins. If these three principles are fully grasped, the mortality from pulmonary embolism is sure to be greatly reduced.

By this time it has become clear that pulmonary embolism rarely occurs unless some sort of phlebitis, usually phlebothrombosis, exists. The real prevention of pulmonary embolism therefore resolves itself into prevention of phlebitis. This can best be achieved by mandatory exercise of the lower legs, beginning immediately after the patient takes to his bed. It has been established that a close connection exists between the slowing up of the venous circulation and the formation of phlebothromboses. The object therefore is to accelerate the venous circulation by suitable exercises. An eminent physician has gone so far as to install bicycle pedals at the foot of the bed. This is effective but is impractical in a large hospital. The same beneficial result can be obtained by instructing the patient to simulate the pedaling motions of cycling. In my opinion a routine extension and flexing of the ankle and knee is just as effective. Something must be done to keep the venous circulation of blood at the normal rate. Under this heading come elevation of the legs in the Trendelenburg position for one hour twice daily, the use of nonconstricting abdominal dressings and routine deep-breathing exercises.

The literature clearly indicates that the maintenance of fluid balance is vitally important. This rationale is based on the fact that a dehydrated patient has a slower circulatory rate. It is imperative to keep a charted record of intake and output to maintain the fluid balance scientifically.

Since patients having varicose veins have been shown to be especially likely to develop superficial and deep phlebitis, it seems logical that if a patient has varicose veins they should be ligated, divided and injected before the fifth month of pregnancy, or prior to any elective operation. This comparatively simple treatment has been shown by many investigators to reduce the menace of pulmonary embolism. Warning must, however, be given that no varicose veins should be injected with a sclerosing solution without a preliminary ligation and division of the great saphenous vein. Failure to take this precaution has resulted in a number of deaths from pulmonary embolism.

Surgical trauma is a factor in causing phlebitis. Rough handling of tissues, leaning on the patient, especially over the femoroiliac region in abdominal operations, and poor approximation of tissues are possible contributory agents in failure to re-establish the normal venous return. For the same reason the holding of the legs is advisable in long gynecologic and obstetric operations are preferable to the use of stirrups. In addition, patients should also be out of bed and walking after a period of observation before the actual operation takes place. They should be made ambulatory by the third day after operation, especially elderly patients.

Many authorities, basing their conclusions on recent findings in biochemistry, look forward to the day when phlebitis will be prevented, or at least successfully treated, by the use of anticoagulant drugs. The medical literature is beginning to resound with claims made for heparin and dicoumarol,

both of which have the significant property of preventing the formation of blood clots. FRANK BURR MALLORY*

A Doctor of Physicians

WILLIAM FREEMAN, M.D.†

WORCESTER, MASSACHUSETTS

The list of former orators of this society shows that never has a pathologist been honored in this manner. The laboratory man can now feel that he has been elevated from the group of "am-nots" to that select fraternity from which orators are chosen. I am deeply appreciative that you have given me the honor of being your orator on this occasion.

Very few if any of those present have not heard of Frank Burr Mallory. I venture to say, however, that very few know him as the physician and inspiring teacher that he was, and probably very few appreciate the tremendous influence his work had in lifting the practice of medicine from the treatment of symptoms to the more effective treatment of causes.

Dr. Mallory was born on November 12, 1862, in Cleveland, Ohio. His father, George Burr Mallory, was a sailor on the Great Lakes all his life, becoming in later years captain of his ship. His mother, Anna Faragher, was born on the Isle of Man, and it was largely through her influence and perseverance that her two children went to college. Eleanor, the daughter, became a schoolteacher. She is now retired and living in Florida. Frank attended the public schools of Cleveland and matriculated at Harvard College, where he earned his way by waiting on table in the dining hall. He was graduated with an A.B. degree at twenty-four years of age. He later attained an M.A. degree there, and in 1890 he received his M.D. degree. He paid his own way at medical school also, this time by doing technical work in the Department of Histology, a circumstance that undoubtedly started his interest in stains and histologic methods.

Immediately after graduation Dr. Mallory was appointed assistant in histology and had some sort of internship at the McLean Hospital, Waverley, where, from what can be learned, he spent most of his time feeding unco-operative patients by stomach tube. He then opened an office for the practice of medicine, but became discouraged when after several months without a single patient a young woman paid him an office visit for the express purpose of having an abortion performed.¹

In 1891 he embarked on his career. At about the same time Dr. William T. Councilman, newly selected Shattuck Professor of Pathology at the Harvard Medical School, was appointed pathologist at the Boston City Hospital. Dr. Mallory was made

Dr. Councilman's assistant, both at the medical school and at the hospital.

At that time the morgue and autopsy room at the Boston City Hospital were located in the boiler room on Albany Street, and the dead patients had to be carried from the hospital on a stretcher across this busy thoroughfare. This practice became so objectionable that it was decided to move the morgue and autopsy room to the hospital grounds. The singular choice of the second floor of the laundry building was made for these rooms, and although no public streets had to be crossed, the dead bodies had to be carried up a long, winding, narrow stairway.² Largely through the efforts of Dr. Councilman and Dr. Mallory, the city government finally agreed to the construction of a separate laboratory and mortuary building. When completed this structure was one of the most modern in this part of the country.

Shortly after this accomplishment, Dr. Mallory was married. He took his wife, Persis McClain Tracy, of Chautauqua, New York, to Europe for a honeymoon and spent it by working a year with Chiari in Prague and Ziegler in Freiburg. On his return in 1894 he was made an instructor in pathology at Harvard.

In 1896 came a series of far-reaching events. Dr. Mallory was promoted to assistant professor of pathology at the medical school, the new laboratory building at the hospital was formally opened, he was appointed first assistant to Dr. Councilman, and his first child, Tracy Burr Mallory, was born. The previous year Dr. J. Homer Wright had come from Baltimore and had been appointed second assistant to Dr. Councilman and assistant at the medical school. Dr. Mallory formed a lifelong friendship with Dr. Wright, and the two collaborated in many scientific and literary adventures. In 1900 another significant event occurred—a second son, George Kenneth Mallory, was born. A year later Dr. Mallory became an associate professor of pathology at Harvard. Dr. Councilman resigned in 1908 as pathologist at the hospital, and Dr. Mallory was appointed to that position. He later resigned from his teaching position at Harvard but became professor of pathology in 1928. In 1932, at seventy years of age, he became professor emeritus, as well as consulting pathologist at the Boston City Hospital.

Dr. Mallory received many honors during his lifetime, a telling reflection of the world-wide reputation he had attained in medical research. A brief list of these events is presented because they

*The annual oration delivered at the one hundred and fiftieth anniversary of the Worcester District Medical Society, April 12, 1944.

†Pathologist and director of laboratories, Worcester Hahnemann Hospital and Worcester State Hospital; instructor in pathology, Boston University School of Medicine.

testify to the significance that was attached to his work. He was an active member in many national medical societies and had been a moving force in the formation of several, among which were the American Association of Pathologists and Bacteriologists and the American Association for Cancer Research. He served as president and treasurer of the American Association of Pathologists and Bacteriologists, and until 1940 was editor-in-chief of its publication, the *Journal of Medical Research*, which later became the *American Journal of Pathology*. He was also elected an honorary member of the Pathological Society of Great Britain and Ireland and a corresponding member of the Royal Medical Society of Budapest. He was awarded the Ernst gold-headed cane of the American Association of Pathologists and Bacteriologists for specially meritorious work in pathology. He was the third man to be so favored by the society, the two previous awards having gone to William H. Welch and to Theobald Smith. Tufts College and Boston University each conferred on him the honorary degree of Doctor of Science. In 1935 he received the Kober Medal from the Association of American Physicians. He lectured by invitation before medical societies in many parts of this country.

In 1933, a year after his retirement, the City of Boston honored Dr. Mallory by erecting a modern laboratory building as a memorial to his untiring work and achievements. The Mallory Institute of Pathology at the Boston City Hospital stands today as a completely equipped institution for the study of pathology and for the training of men interested in this branch of medicine.

These are the high lights in Dr. Mallory's pervasive career in medicine. Although they serve for orientation, they no more than throw a hint concerning the import of his work. For a clearer appreciation of the latter one must probe deeper and study him in his varied works and interests.

Austerity is almost a requisite in people's mental picture of a scientist, and to those who did not know Dr. Mallory he appeared to be true to type.³ His credo was that the only way to do good work is to make that work an obsession and to avoid extracurricular activities, and since his pleasures were not such as to be related to social life, he seemed to others to live the life of an ascetic. He loved the outdoors and everything pertaining to life itself, however, — a characteristic that was probably inherited from his father. Early in life he developed an interest in botany, and nothing pleased him more than a tramp in the woods or a leisurely canoe ride when he would study the plants and flowers that he encountered. Almost every Saturday afternoon was devoted to these trips. He was a tennis enthusiast and could play a fast and scientific game. Whenever attending a match of professionals, he was more interested in their form

than in the score. When increasing age interfered with strenuous activities, he continued his daily walks, even up to a few months of his death. At home the early evening was often spent playing a piano duet with the elder of his sons. Such was the simplicity of living of this great man, a simplicity that allowed him extra time for work, for study and for thought.

It must be remembered that at the time Dr. Mallory began his professional career, scientific medicine, so called, was in its infancy. Illness was treated primarily according to symptoms, and there was little knowledge regarding the cause of the symptoms. Practically nothing was known about the tissue changes occurring in disease. The work of Pasteur and Jenner was known, but Virchow, the father of modern pathology, was in the midst of his labors, Koch was in the process of discovering the tubercle bacillus, Ehrlich was yet to discover salvarsan, and bacteriology was only approaching the heyday of its morphologic phase. With the great impetus given the search for causes by the success of investigators in bacteriology, it is probable that Dr. Mallory visualized the great need for studying the cause of disease so that it could be attacked directly rather than be treated on the basis of its symptoms alone. In studying the organs of a person who had died of a disease he visualized the immense opportunity that was afforded in helping his clinical colleagues treat and cure their patients more effectively. Cellular pathology was to him the key to the cause of disease, for it was in the cells, "the building blocks," that changes all the way from health to illness should be reflected. Given the proper tools, he believed that it should be possible to view the changes wrought in the cells, and from this it should be possible to reconstruct the destructive action and treat for it. But first tools were needed — highly sensitive tools. Here it can be stated that if Dr. Mallory had accomplished no more than his work on stains and histologic technics, he would still have been a great scientist, to such a high degree of perfection did he develop them.

It is probable that Dr. Mallory's early experience in the Department of Histology, while working his way through Harvard Medical School, created his first interest in the staining and fixing of tissues. He often reiterated that the perfect stain for the perfect section would reveal the basic essentials for the study of any disease, but conversely the imperfect stain and the imperfect section could only result in false observations and false conclusions. Mallory's staining and histologic technics, brilliant in conception and results, were developed only after tedious work and exhaustive experimentation. His experiments on this subject continued throughout his career. His work at the Boston City Hospital afforded him ample opportunity for improving and perfecting these technics and for demonstrating that they were usable in a routine laboratory. The

sheer wizardry that can convert a commonplace lesion stained by ordinary methods into a thing of beauty and distinction when put through one of his specific stains for cellular substances seems like a page out of a fairy tale.³

Of the more important discoveries he made in this connection are differential stains for *Endameba coli*, neuroglia fibers, collagen fibers, muscle tissue and connective tissue. He also developed methods for the detection of certain metallic poisons in tissue cells.

There arose a demand for a text on pathological methods, and in 1897 Dr. Mallory collaborated with Dr. Wright to publish the first edition of the now famous *Pathological Technique*,⁴ which has been the standard work on histopathology since its first appearance. It passed through eight editions and could be found on the bookshelf of almost every medical laboratory in America and Great Britain. After Dr. Wright died, it took many years before Dr. Mallory was finally persuaded to make another revision, the last edition appearing in 1938 and being dedicated to the memory of Dr. Wright. This book contains the most advanced and proved technics for fixing and staining any tissue in the human body and in any disease.

Nonetheless, to Dr. Mallory the correct preservation and staining of pathologic tissue was only a tool with which to study diseased cells. The intense urge to study the changes in tissue cells from the onset of a disease to its end drove him to persistent and tenacious work. In 1914 he published his great book, *The Principles of Pathologic Histology*,⁵ the result of years of experience and study. In the preface he stated that he was dealing with pathology from the morphologic standpoint and that his aim was to present the subject biologically, first by ascertaining the cells out of which various lesions are built, and then by tracing the development of the lesions from the simplest to the most complex forms so that at the autopsy or surgical table it could be read backward with some degree of certainty. As in all his publications, the text is liberally interspersed with beautiful drawings and photomicrographs in which the histologic pictures presented leave no one in doubt concerning the entities discussed.

At the turn of the century, when photography offered an advancement in pictorial delineation, Dr. Mallory was the first to use it in his publications. Characteristically, he studied and perfected photomicrographic technic until he was an expert. From then on all his publications were illustrated by exquisite photomicrographs. Furthermore, he insisted that all papers published in the journals of which he was editor be adequately and pertinently illustrated with the best photographs obtainable. Dr. Mallory often said that good photomicrographs should represent the perfect section, the perfect stain and the perfect microscopic field.

He further stated that he himself spent more time in selecting the section, the stain and the field than in writing the paper itself. Yet his sentences and phrases were also meticulously selected for simplicity and lucidity.

Mallory's hypothesis of cellular building blocks did not come out of thin air, a single case or a moment of armchair philosophy. In fact, he had an abhorrence of armchair theorists,⁶ and he insisted that each pathologist should base his theories only on careful study of the given disease in its many variations. In 1895 he himself started a study of the lesions of typhoid fever that was not completed until three years later. His published findings are as much an example of his careful and tenacious work and study as they are a classic report of the tissue and cellular changes pathognomonic of the disease so widespread in that day. Since at that time photomicrography was not yet known, he enhanced the clarity and comprehensiveness of his findings by a generous use of drawings of both the gross and microscopic lesions. So definitive was his study of the pathology of this disease that any well-trained pathologist can today diagnose a case of typhoid fever post mortem even though the causative bacterium has not been isolated.

Genius has been described as the infinite capacity for taking pains.³ Certainly Dr. Mallory's long and conclusive study of cirrhosis of the liver would qualify him as a scientist of surpassing genius even if it were the only work that typified his perseverance, the exactness of his technic and his thoroughness in exhausting all possible leads.

Cirrhosis of the liver was formerly a disease that was obscure in cause, more obscure in diagnosis and even more so in its nomenclature. Each type of cirrhosis was named after the particular writer who described a case or group of cases, and as Dr. Mallory later proved, most of these diseases were either the same type of cirrhosis or different stages of the same type. He believed that much was lost in studying the late stages of sclerotic liver disease, and hence he planned to study the onset and course. He expended more than twenty years of labor before he felt qualified to release his findings and give forth his conclusions. He first revealed that there are five distinct lesions from which cirrhosis can be derived. He then proved, with the aid of his differential stains, that hyalin is a pathognomonic finding of the liver-cell cytoplasm in so-called "alcoholic cirrhosis" of the liver. Then began his search for the cause of this type of disease.

In trying to find out whether addiction to alcohol did indeed produce cirrhosis of the liver, Dr. Mallory fed laboratory animals alcohol for many years. He finally concluded that ethyl alcohol per se is not the cause of alcoholic cirrhosis of the liver. Then followed years of painstaking work and disappointments in the search for the actual cause of this type of liver disease. Any less able man would have been

discouraged. When he believed that he could go no farther in his studies by the use of differential stains and cytologic methods alone, he resorted to animal experimentation. As new species of animal successively failed him, he tried another and still another. Finally, after nearly a quarter of a century of toil, he proved beyond all doubt that a certain type of cirrhosis of the liver can be caused by minute amounts of copper or phosphorus, but he was never able to explain satisfactorily the cause of alcoholic cirrhosis.

The abundant pathologic material from the South Department of the Boston City Hospital served as a basis for studies on the tissue changes in many contagious and infectious diseases, and it must not be supposed that Dr. Mallory neglected bacteriologic technics because of his fundamental, almost obsessive, interest in tissue studies. The bacteriologic and serologic technics used in his laboratories were the best and the most up to date, but they were used only as a means for rapid diagnosis and for proof of the etiology of the disease in which he studied the tissue changes. He contributed a chapter on the pathology of diphtheria to a book published by the Cambridge University Press, and made similar contributions on scarlet fever, measles and whooping cough. All cases coming to autopsy in his department received the same careful study and thought.

Dr. Mallory had to be sure of his ground before he published any findings. He meticulously followed all leads and considered all possibilities to determine which idea or ideas were tenable and which should be discarded. This sometimes led him into quite different byways; for example, his careful study of the cellular changes found in typhoid lesions led him to the discovery that endothelial leukocytes are phagocytic cells derived from the endothelium lining the blood vessels and vascular spaces. Although it is true that Metchnikoff's theory of phagocytes had been postulated some years before, it was from this that the true origin of Metchnikoff's macrophages was first learned, and it was from the results of his studies that Aschoff derived his concept of the reticuloendothelial system.

As the surgical removal of tissues and organs from the living body became more frequent, it was natural that Dr. Mallory spent more and more time and study on the cellular changes found in these specimens. His studies on the morphologic characteristics of neoplasms are another milestone in the advance of medical knowledge on this subject, for they resolved the confusion that was associated with neoplasms at that time. The current belief was that neoplastic cells were a sort of spontaneous and mysterious new life produced for its destruction of the host. The names attached to the various tumors found occurring in the human body were varied and meaningless, and oftener than not a

hitherto unpublished tumor had the discoverer's name attached to it. It is needless to point out the chaos inherent in such a situation. It was Dr. Mallory who by his characteristic methods of study proved that the cells of any tumor are derived from one of the three embryonic layers and that they thus have a definite histologic reference. From these findings he devised a system of nomenclature for neoplasms that was based on a firm scientific foundation and that could be understood the world over. These facts are not only of academic interest but also of the utmost clinical importance, for through them all the mystery regarding the origin of neoplasms was removed and it became possible to build an equally firm system of diagnosis and treatment.

The few studies described here in more or less detail are typical examples of the many adventures of Dr. Mallory in medical research. Whereas his contributions in the field of laboratory medicine are admitted by all to have been of outstanding and far-reaching importance, he himself was more concerned that his researches have significance to the clinician. That his investigations and findings should help other physicians in treating and curing disease was ever his immediate goal. He was among the first to recognize the need for studying the causes and symptoms of disease to derive practical clinical benefit therefrom. His contributions laid the foundation for the treatment of causes rather than of symptoms alone, and as such they are one of the greatest factors in the phenomenal advance of medicine in the last thirty years. They epitomize the change from an empirical to a scientific concept of medicine.

While Dr. Mallory was the pathologist of one large hospital and the consultant pathologist of many other hospitals, he was also the unofficial consultant to a great army of pathologists and clinicians throughout the world, and his diagnosis and opinion were always given freely, after careful study, and were devoid of self-conscious authority.

Aside from all these achievements, there was one aspect of his work that to Dr. Mallory meant more than all the others put together; this was his training of pathologists. On the commemoration of his fiftieth year after graduation, he wrote in his college yearbook, "Aside from the problems of my own work, one of my greatest pleasures has been in training young men and women in pathology and in seeing what they could make out of themselves under proper encouragement and stimulation; in other words, in getting them to do their own thinking and to work out their own salvation." Graduate physicians who came to study pathology with him found Dr. Mallory the inspiring teacher par excellence. To his students he gave all he had, and he attended to their training personally.

Severe in appearance and strict in his work though he was, Dr. Mallory was intensely human. In addition to his two sons, he had an army of

MEDICAL PROGRESS

SULFONAMIDE THERAPY IN OTOLARYNGOLOGY

ROBERT L. GOODALE, M.D.*

BOSTON

THE purpose of this review is to present the trend of thought in regard to sulfonamide therapy as it relates to otolaryngology. As a preface to the subject, attention should be called to two contributions that are helpful in evaluating the role of chemotherapy.

In a study of the outpatient records at the Massachusetts Eye and Ear Infirmary covering the five-year period 1937-1941, Richardson¹ records the clinical course of 645 cases untreated by sulfonamides. He charts the cases according to the bacteriology found at early paracentesis and to the duration of infection of those cases that did not go on to a surgical mastoid. In the cases in which hemolytic streptococci were found, he notes that 36 per cent did not heal until the fourth, fifth or sixth week. Cases with pneumococcal infection healed in an average of twelve days. In *Staphylococcus aureus* or *Staph. albus* infection the average duration of the discharge was ten days. In this series the incidence of mastoidectomy was as follows: hemolytic streptococcus, 10 per cent; pneumococcus, 4 per cent; and staphylococcus, 5 per cent.

Dean² reviews the literature of otitis media historically and presents figures from early authors regarding the mortality attending otitis media in the days before modern surgery and chemotherapy. He quotes Körner, who in 1902 published statistics for Prussia at the end of the nineteenth century and stated that from birth to ten years of age only 0.22 per cent of all deaths were attributed to otitis media. In the second decade 5.15 per cent, in the third decade 3.85 per cent, in the fourth decade 1.44 per cent and above forty years 0.27 per cent were otitic deaths. Dean writes that Bezold commented that these early statistics were actually too low because the pathologist usually did not examine every ear unless his attention was drawn to it. Dean quotes Dublin, statistician of the Metropolitan Life Insurance Company, to the effect that in 1940 in the United States the ratio of deaths due to ear infection to those from all other causes was 1:337, or 0.29 per cent, which compares with Körner's average figure of 1.05 per cent for all decades. Of course, in such a comparison the decrease in infant mortality, as well as the increase in longevity for the whole population, must be taken into account.

It is important to mention these facts inasmuch as sulfonamides are now so generally used at the

very onset of otitis media and in some clinics routinely, as well as preoperatively and postoperatively, that the student and the intern do not have a proper picture of otitis media as it existed prior to the introduction of chemotherapy.

Lindsay,³ in a review of recent progress in the treatment of acute otitis media, summarizes the present-day management. He states that the most effective time for chemotherapy is in the invasive stage. He prefers sulfadiazine, and urges that the initial doses should be gauged to obtain an early concentration in the blood of 6 to 10 mg. per 100 cc. This level should be maintained for two or three days, although the time to lower the concentration should be determined by the clinical condition. He states, nevertheless, that if certain indications are present before chemotherapy the best interest for the patient demands that surgery be carried out.

Hall and Spink⁴ advocate the use of sulfamerazine, and give the following directions for its administration. In adults and large children, 3 to 4 gm. is given as an initial dose, followed by 1 gm. every six hours until the temperature has been normal for forty-eight hours; then 0.5 to 1 gm. is given every eight hours and discontinued on the fifth to seventh afebrile day. In small children, 0.05 gm. per pound of body weight (the total not to exceed 4 gm.) is given initially, and treatment is continued with a dose of 0.05 gm. per pound of body weight in divided doses until the temperature is normal; then the dose is gradually reduced and is discontinued on the fifth to seventh afebrile day. In discussing the use of sulfamerazine it is stated that it is just as effective as sulfadiazine but requires smaller doses given less frequently and does not appear to be more toxic than sulfadiazine. The first point is important when it is desirable not to wake the patient for medication at night.

Ruskin⁵ advocates the addition of vitamin C to sulfonamide compounds, in the form of either sulfanilamide ascorbate or sulfathiazole ascorbate, in the treatment of chronic suppuration of a wound after mastoidectomy because of the known effect of vitamin C in hastening the healing of wounds.

Kolmer,⁶ in discussing the principles of treatment with sulfonamide compounds, says that the indiscriminate use of sulfonamide compounds is to be regretted because of the possibility and even the probability that the pathogenic bacteria will acquire resistance to the compounds. In using

*Instructor in laryngology, Harvard Medical School, associate surgeon, Massachusetts Eye and Ear Infirmary.

them for secondary bacterial infections of the common cold he quotes Spink,⁷ who states that chemotherapy should not be used in this group of infections except in patients with severe infections actually caused by hemolytic streptococci; in patients who are known to have cardiac defects, with the hope of being able to forestall bacterial endocarditis, and in obstetric patients who have contracted infection of the respiratory tract at or near term. Kolmer also asserts that treatment with sulfonamide compounds is not always a 'short cut to control of the disease, and he quotes Porter,⁸ who states that the otolaryngologist should not overlook prompt and adequate surgical measures, especially in cases in which there is pus to be drained or necrotic bone and infected thrombi to be removed. He believes that the use of sulfonamide compounds should be based on a bacteriologic diagnosis and gives the following list, in order of preference: staphylococcal infections, sulfathiazole and sulfadiazine; hemolytic streptococcus infections, sulfadiazine, sulfanilamide and azosulfamide; infections with *Streptococcus viridans*, sulfapyridine; pneumococcal infections, sulfadiazine; meningococcal infections, sulfadiazine and sulfanilamide; infections with Friedländer's bacillus, sulfadiazine and sulfapyridine; infections with *Pseudomonas pyocyaneus*, sulfanilamide and sulfathiazole; and infections with *Haemophilus influenzae*, sulfadiazine and sulfanilamide.

Much of the recent literature pertaining to the use of sulfonamides in otology is concerned with its use locally in surgical wounds. In a recent article Johnson and Spence⁹ record their experiences in 44 cases of acute mastoiditis in which the patients were treated by means of primary closure of the wound after filling the cavity with sulfonamide powder. They lay great stress on the necessity for a complete xenteration of the mastoid process. Great care should be taken to remove all infected cells. The perilyabyrinthine cells are removed until the horizontal semicircular canal is sharply defined. The zygomatic area is thoroughly cleaned out. In a number of cases the incus is brought into view. The mastoid cavity is then irrigated with normal saline solution, followed by thorough drying of the cavity and complete hemostasis. The cavity is then filled with sulfonamide powder. The wound is closed in two layers, more powder being dusted between the layers. In 12 cases in which one of the authors (L. F. J.) operated, there was complete healing of the postaural wound and resolution of the drum in twelve days. In another group of 8 cases operated on by various members of the hospital staff, the average postoperative stay was fourteen days. Twenty-five cases in which the mastoiditis had occurred secondary to scarlet fever had an average postoperative stay of twenty-eight days. A fourth group of 26 patients, used as a control, had an average stay of over fifty-two days, 24 of

these cases being secondary to scarlet fever. It should be noted that these authors advocate a thorough surgical technic, and it seems likely that incomplete surgery, more than anything else, prolongs the healing of mastoid wounds.

Livingston¹⁰ likewise recommends the use of sulfanilamide and sulfathiazole in postoperative mastoid cavities, but he states that in chronic cases sulfathiazole powder, although diminishing the odor and the purulent nature of the discharge, increases the discharge in quantity and that the caked powder often presents a problem. In cases of cholesteatoma the drug in no way alters the pathologic picture. Sulfonamide treatment hastens the healing in radical sinus surgery.

There is an increasing tendency to recognize the injurious effects of sulfonamide treatment. At the present time the serious effects of overdosage, such as agranulocytosis, severe anemia and renal damage, are well known. In otolaryngology there are other disadvantages. Because of the danger of sensitization nearly all authors now deprecate the use of sulfonamides for minor self-limited upper respiratory infections. It is true that during the present emergency civilians employed in essential war work have been under great pressure, particularly on the part of their employers, to remain at their work, even in the face of severe upper respiratory infection. Absenteeism has been so denounced that many people hesitate to report their illnesses. Among these the use of sulfonamide sprays, as well as the oral administration of these drugs, has been practiced.

Lessard¹¹ condemns the practice of those who have a tendency to give sulfonamides to patients at the slightest alarm, and cautions that should a later infection, such as meningitis or pneumonia, occur in a sensitized person, the use of sulfonamides would be impossible.

Livingston¹⁰ states that the problems that the otolaryngologist frequently encounters are as follows: previous inadequate administration; wrong choice of drug; infection refractory to sulfonamides; difficulty of differentiating an exacerbation of the infection and symptoms due to drug toxicity; and the masking effect of sulfonamides.

Leftwich,¹² recognizing the tendency of sulfonamide drugs to produce a hypersensitive reaction, states that most attempts to demonstrate sensitivity to sulfonamides by means of skin tests have failed. His studies were made on 76 patients at Johns Hopkins Hospital from March to July, 1943. The ability of the sulfonamides to combine with the plasma proteins suggested that, attached to the plasma proteins, they may act as haptens and in this way specifically sensitize the body. He writes:

Thinking along these lines it seems reasonable to suppose that there could be produced in the blood of the individual receiving a sulfonamide therapeutically, with an effective blood level, an antigenic substance capable

of causing sensitization in some instances, and possibly able to produce an allergic skin reaction when the serum of such an individual is injected intradermally in a person who is hypersensitive to the homologous sulfonamide. . . .

More than three hundred intradermal tests have been performed on the 76 patients studied, using forty different samples of serum as the testing agents. . . . These sera were obtained from patients suffering from some acute bacterial infection who had been treated with one or another of the drugs, whose blood cultures were negative and in whom the serologic test for syphilis was negative.

The serum was separated from the blood and placed in sterile rubber-stoppered containers, 0.5 cc. also being added to a culture medium, which was incubated for seventy-two hours as a check for sterility. The test was made by injecting intracutaneously into the flexor surface of the forearm 0.05 cc. of a control (normal) serum and 0.05 cc. each of serums from several of the patients treated with sulfonamides.

This test was found to be reliable in the diagnosis of drug sensitivity in 28 of 30 patients who had experienced definite drug reactions. It was positive in only 1 of 8 patients who were thought to be questionably sensitive clinically. In 26 patients in whom there was no evidence of sensitivity, the test was negative in 24. The 2 patients in this group who had positive tests had received sulfon-

amides for periods longer than six days so they may have been subclinically sensitized. Leftwich concludes that this method will show by a positive skin test whether or not a patient is sensitized to a specific sulfonamide, and also that this test is additional evidence that the drug sensitivity is an allergic reaction.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE COUNCIL

Stated Meeting, October 4, 1944

A STATED meeting of the Council of the Massachusetts Medical Society was held in John Ware Hall, 8 Fenway, Boston, on Wednesday, October 4, 1944.

The meeting was called to order at 10:00 a.m. by the president, Dr. Elmer S. Bagnall, Essex North; 204 councilors were present (Appendix No. 1).

The Secretary presented the record of the meeting of the Council held on May 22, 1944, as published in the *New England Journal of Medicine*, issue of July 27, 1944.

Dr. John Homans, Suffolk, moved its acceptance and approval. This motion was seconded by Dr. Albert A. Hornor, Suffolk, and it was so ordered by vote of the Council.

REPORT OF THE EXECUTIVE COMMITTEE

The Secretary, in presenting the report of the Executive Committee (Appendix No. 2), said that the committee, in the name of the Massachusetts Medical Society, had endorsed the Fifth War Loan Drive and referred a telegram from Dr. Olin West, secretary of the American Medical Association, concerning it to the Committee on Finance.

He spoke of a question that had arisen in the committee as to the legality of the Council's action in adopting one of the recommendations contained in the report of the Committee on Medical Information Bureau. This recommendation had to do with an appropriation of \$2500, which was granted by the Council for the use of this committee. It was contended that the recommendation, calling for this appropriation, should have been first submitted to the Committee on Finance; failing in this, the Council should have made the appropriation contingent on its approval by this committee. The report went on to say that the committee instructed the President and Secretary to examine this situation. In the event that the appropriation had been improperly made, the President was urged to exercise his emergency powers so as to make this money available.

The report went on to say that the members of the committee were in receipt of an opinion on this matter written by the President which, in substance, stated that there was manifest evidence in the by-laws to the effect that it is the intention to have the Committee on Finance scrutinize any proposals for the expenditure of monies that are

extraordinary or other than routine. The Secretary added that the opinion also said that there is precedent for the appropriation of monies directly by the Council but that this has been contingent on the appropriation's approval by the Committee on Finance. The Secretary said that the President had exercised his emergency powers and that the money in question was available for the use of the Committee on Medical Information Bureau.

The report spoke of a request made by Mr. Powell M. Cabot, Massachusetts director of the War Manpower Commission. Mr. Cabot asked that the Massachusetts Medical Society set up machinery to aid his department similar to that set up to aid the Massachusetts director of the OPA. The report continued that this matter had been referred by the Executive Committee to the War Participation Committee, with instructions to co-operate with the Massachusetts director of the War Manpower Commission.

The report spoke of two communications that had been received on the same subject: one from the deputy surgeon general of the United States Army, Dr. George F. Lull, and the other from Lieutenant Colonel Mark C. Elworthy, chief of the Procurement Division. These communications concern a change in policy of the office of The Surgeon General whereby the Army is now commissioning certain graduates of Middlesex University School of Medicine. The conditions under which such commissions are granted are indicated in the body of the report.

The Secretary said that the committee had approved a plan submitted by the Red Cross for the training of volunteer nurse's aides in the treatment of infantile paralysis patients in the noncommunicable stage of the disease. He added that this matter had been submitted to the Committee on Public Health, which body had approved such action. He moved that the Council do likewise. This motion was seconded by Dr. David Cheever, Suffolk, and it was so ordered by vote of the Council.

Finally, the report said that the committee had reviewed the report of the Committee on Public Relations and had approved the recommendations contained therein, and certain *ad interim* appointments made by the President.

The Secretary moved the adoption of the report as a whole. This motion was seconded by Dr. Roy J. Heffernan, Norfolk, and it was so ordered by vote of the Council.

REPORTS OF STANDING COMMITTEES

Committee on Publications — Dr. Richard M. Smith, Suffolk, chairman.

No report.

Committee on Arrangements — Dr. Roy J. Heffernan, Norfolk, chairman.

The report, which was offered by Dr. Heffernan, is as follows:

The Committee on Arrangements, while recognizing the advisability of holding the annual meeting of the Society in various parts of the Commonwealth, believes that, owing to wartime restrictions on travel and to the limitations of hotel accommodations that may prevail next spring, it will be best to hold the 1945 annual meeting in Boston at the Statler Hotel.

It has also been thought advisable by your committee to increase the length of the meeting from two to two and a half days. To accomplish this the meeting will start on the afternoon of Tuesday, May 22, and continue through Wednesday and Thursday, May 23 and 24.

The annual meeting of the Council will be held Tuesday evening, May 22.

Dr. Heffernan moved the acceptance of the report. This motion was seconded by Dr. Cheever, and it was so ordered by vote of the Council.

Committee on Ethics and Discipline — Dr. Ralph R. Stratton, Middlesex East, chairman.

No report.

Committee on Medical Education — Dr. Robert T. Monroe, Norfolk, chairman.

No report.

Committee on Membership — Dr. Harlan F. Newton, Suffolk, chairman.

No report.

Committee on Public Health — Dr. Roy J. Ward, Worcester, chairman.

The report, which was offered by Dr. Ward, is as follows:

The Committee on Public Health has had two meetings, both during the summer months. The committee is mindful of the contributions which the Society has made to public health in the past and hopes that further contributions can be made.

The first meeting was to explore the possibilities for concrete activities.

The second meeting discussed at length the proposed rheumatic-fever program of the Massachusetts Department of Public Health. The department is now rewriting the plan embodying recommendations of the committee, and it will be resubmitted to the committee later. The committee believes that the Department of Public Health earnestly desires the co-operation of the Society and is making every effort toward that end.

This is only a report of progress.

Dr. Ward moved the acceptance of this report. This motion was seconded by Dr. Guy L. Richardson, Essex North, and it was so ordered by vote of the Council.

Committee on Medical Defense — Dr. Arthur W. Allen, Suffolk, chairman.

No response.

Committee on Society Headquarters — Dr. J. Harper Blaisdell, Middlesex East, chairman.

Dr. Blaisdell, in offering this report, said that it contained no recommendation. He expressed the desire, however, to pass on to the Council certain information on and comments concerning the Society's headquarters. He added that the question of the site of such headquarters was a closed book.

for some time, a lease between the Society and the Boston Medical Library having been signed on October 1, 1943, to cover a period of five years. He said that this lease had been signed, on the part of the Society, by Dr. Roger I. Lee, at that time the president, and by Dr. William H. Robey, at that time the chairman of the Committee on Society Headquarters. By the terms of the lease, he continued, the Society pays the sum of \$6500 per year for the use of 3262 feet of floor space. It has the free use of John Ware Hall and one or two other halls including the banquet hall in the basement. He said that the rental was at the rate of \$2.00 per square foot. He expressed the thought that this was a generous rent.

He said that, during the summer, his committee had met with the Committee on Medical Information Bureau and that it had been proposed to set up the bureau in a space obtained by dividing up the present quarters of the President and Secretary. He added that, inasmuch as the Information Bureau was in the nature of an experiment and space elsewhere could be provided for it at the moment, it would be better to postpone any permanent partitioning. He said that this partition would cost at least \$800 and that this was another element influencing the committee's judgment.

He said that there was nothing on the outside of the building to indicate that therein was housed the headquarters of the Massachusetts Medical Society.

Finally, Dr. Blaisdell spoke of a meeting that the president, Dr. Elmer S. Bagnall, had arranged for that night with a gentleman who had just come into the service of the Massachusetts Dental Society and to which the Committee on Society Headquarters had been invited. He added that the gentleman in question is an expert on society headquarters, on publicity and on general relations between the professions, the press and the public.

The President announced that no vote on this report was necessary. He asked for a discussion of this report by way of questions or suggestions directed toward the committee. There was no response.

Committee on Finance — Dr. Francis C. Hall, Suffolk, chairman.
No response.

Committee on Industrial Health — Dr. Dwight O'Hara, Middlesex South, chairman.
No report.

REPORTS OF STATE-WIDE COMMITTEES

Committee on Legislation — Dr. Brainard F. Conley, Middlesex South, chairman.

Dr. Conley said that, inasmuch as last year was an off year in legislative matters, the committee had no report to offer.

Committee on Public Relations — Dr. Albert A. Hornor, Suffolk, secretary.

The report (Appendix No. 3) was offered by the secretary of the committee. The committee reported progress in two items: first, in the matter of better publicity for the Massachusetts Medical Society and, second, in regard to discussions held with the Massachusetts Division of Unemployment Security concerning sickness insurance for those employed in industry.

The report spoke of a discussion that had taken place between the members of the committee, representatives of the New England Roentgenological Society, the executive director of the Blue Cross, the administrator of the Waltham Hospital, the director of the Blue Cross and the president of the Massachusetts Hospital Association. This discussion concerned a proposed plan of the Blue Cross to include in the benefits offered under its contracts the sum of \$15.00 toward the costs of x-ray examination that the individual policyholder might require while hospitalized. In regard to this matter two recommendations were offered by the committee: first, that the Council should not approve, at present, the proposed plan of the Blue Cross to pay \$15.00 toward the costs of x-ray examinations in hospitals and, second, that discussion by the Massachusetts Hospital Service, Massachusetts Hospital Association, New England Roentgenological Society and the Committee of the Massachusetts Medical Society to Meet with the Massachusetts Hospital Association — Dr. Walter G. Phippen, chairman — should be continued.

Dr. Hornor moved the adoption of the first recommendation. This motion was seconded by Dr. Cheever, and it was so ordered by vote of the Council.

Dr. Hornor moved the adoption of the second recommendation. This motion was seconded by Dr. Richardson, and it was so ordered by vote of the Council.

Dr. Hornor moved the acceptance and adoption of the report. This motion was seconded by Dr. Henry M. Landesman, Norfolk, and it was so ordered by vote of the Council.

The President at that point called on Dr. Charles E. Mongan, senior Massachusetts delegate to the House of Delegates of the American Medical Association, to report on the proceedings of the last meeting of that body (see Appendix No. 4).

Dr. Mongan concluded his report by saying:

Another member of our society has been called to the presidency of the American Medical Association. He is superbly equipped for the office, and well informed as to the nature of problems confronting organized medicine. He has served as member of the House of Delegates for ten years. He has been a member of the Board of Trustees for five years. He has been chairman of the Board of Trustees. He is a practicing physician, and has been president of the American College of Physicians.

extraordinary or other than routine. The Secretary added that the opinion also said that there is precedent for the appropriation of monies directly by the Council but that this has been contingent on the appropriation's approval by the Committee on Finance. The Secretary said that the President had exercised his emergency powers and that the money in question was available for the use of the Committee on Medical Information Bureau.

The report spoke of a request made by Mr. Powell M. Cabot, Massachusetts director of the War Manpower Commission. Mr. Cabot asked that the Massachusetts Medical Society set up machinery to aid his department similar to that set up to aid the Massachusetts director of the OPA. The report continued that this matter had been referred by the Executive Committee to the War Participation Committee, with instructions to co-operate with the Massachusetts director of the War Manpower Commission.

The report spoke of two communications that had been received on the same subject: one from the deputy surgeon general of the United States Army, Dr. George F. Lull, and the other from Lieutenant Colonel Mark C. Elworthy, chief of the Procurement Division. These communications concern a change in policy of the office of The Surgeon General whereby the Army is now commissioning certain graduates of Middlesex University School of Medicine. The conditions under which such commissions are granted are indicated in the body of the report.

The Secretary said that the committee had approved a plan submitted by the Red Cross for the training of volunteer nurse's aides in the treatment of infantile paralysis patients in the noncommunicable stage of the disease. He added that this matter had been submitted to the Committee on Public Health, which body had approved such action. He moved that the Council do likewise. This motion was seconded by Dr. David Cheever, Suffolk, and it was so ordered by vote of the Council.

Finally, the report said that the committee had reviewed the report of the Committee on Public Relations and had approved the recommendations contained therein, and certain ad interim appointments made by the President.

The Secretary moved the adoption of the report as a whole. This motion was seconded by Dr. Roy J. Heffernan, Norfolk, and it was so ordered by vote of the Council.

REPORTS OF STANDING COMMITTEES

Committee on Publications — Dr. Richard M. Smith, Suffolk, chairman.

No report.

Committee on Arrangements — Dr. Roy J. Heffernan, Norfolk, chairman.

The report, which was offered by Dr. Heffernan, is as follows:

The Committee on Arrangements, while recognizing the advisability of holding the annual meeting of the Society in various parts of the Commonwealth, believes that, owing to wartime restrictions on travel and to the limitations of hotel accommodations that may prevail next spring, it will be best to hold the 1945 annual meeting in Boston at the Statler Hotel.

It has also been thought advisable by your committee to increase the length of the meeting from two to two and a half days. To accomplish this the meeting will start on the afternoon of Tuesday, May 22, and continue through Wednesday and Thursday, May 23 and 24.

The annual meeting of the Council will be held Tuesday evening, May 22.

Dr. Heffernan moved the acceptance of the report. This motion was seconded by Dr. Cheever, and it was so ordered by vote of the Council.

Committee on Ethics and Discipline — Dr. Ralph R. Stratton, Middlesex East, chairman.
No report.

Committee on Medical Education — Dr. Robert T. Monroe, Norfolk, chairman.
No report.

Committee on Membership — Dr. Harlan F. Newton, Suffolk, chairman.
No report.

Committee on Public Health — Dr. Roy J. Ward, Worcester, chairman.

The report, which was offered by Dr. Ward, is as follows:

The Committee on Public Health has had two meetings, both during the summer months. The committee is mindful of the contributions which the Society has made to public health in the past and hopes that further contributions can be made.

The first meeting was to explore the possibilities for concrete activities.

The second meeting discussed at length the proposed rheumatic-fever program of the Massachusetts Department of Public Health. The department is now rewriting the plan embodying recommendations of the committee, and it will be resubmitted to the committee later. The committee believes that the Department of Public Health earnestly desires the co-operation of the Society and is making every effort toward that end.

This is only a report of progress.

Dr. Ward moved the acceptance of this report. This motion was seconded by Dr. Guy L. Richardson, Essex North, and it was so ordered by vote of the Council.

Committee on Medical Defense — Dr. Arthur W. Allen, Suffolk, chairman.
No response.

Committee on Society Headquarters — Dr. J. Harper Blaisdell, Middlesex East, chairman.

Dr. Blaisdell, in offering this report, said that it contained no recommendation. He expressed the desire, however, to pass on to the Council certain information on and comments concerning the Society's headquarters. He added that the question of the site of such headquarters was a closed book

creased to cover marginal situations, although the usual reserve will be about 10 per cent.

This plan is open to all banks in Massachusetts, although it was started by the National Shawmut Bank. Some of the banks may adopt a different rate of reserve than others, and there may be a slight variation in the charge for this reserve.

This reserve, the 10 per cent having been taken out, is paid back to the doctor as payment on each account collected, unless the bank has some other charge against that particular physician, in which case the payment is credited against the other charge. As a result of the reserve feature, the term is shortened, so that the yield on the suggested rates compares closely with that of personal loans.

Whereas this has the appearance of collecting by the bank, it must be understood that the plan is in no way similar to the procedure of a collection agency. This plan is for current bills, not for the collection of bad bills. It is simply a method of making it easier for a man who eventually pays his bills to satisfy the legitimate claims of the physician, and to relieve the doctor of repeated monthly statements. It will take time for the plan to become the customary procedure. Over the years its use will expand.

Dr. George L. Schadt, Hampden, asked what was the basis on which the banks would consider a bill to be in the collection category. The President answered the question as follows:

The banks do not believe that it would be profitable for them if doctors took their bills that are five, six or seven years old, dumped them into a basket and gave them to the banks, but I am very sure that there would be no objection if some of these old accounts were turned over. Of course, the bank investigates the credit of each signer, and they will not accept the note unless they feel that there is a probability that the signer will go through. Furthermore the doctor, of course, should not endorse the note unless he thinks that his patient will probably stand behind it.

Dr. Schadt further inquired whether or not the doctor presents his bill to the bank on the completion of his work, whereupon it is paid by the bank, or whether he has to wait one, two or three months for such payment. Dr. Ellison replied that the arrangement can be made with the patient either during or after the illness.

Dr. Donald Munro, Suffolk, asked what the bank received. Dr. Ellison replied that, on amounts under \$100, the bank charges 50 cents a month.

Dr. Munro asked to whom the charge is directed. Dr. Ellison replied, "To the person who is being paid." He added that, if the doctor has a bill for \$100, he can deduct \$6, receiving \$94 in full payment from the bank. Dr. Munro replied that in essence this was a method whereby the doctor pays the bank to collect his bills. Dr. Ellison replied: "If the doctor wants to take out the charge, he is entitled to do so. If he does not, it is added to the amount of the face of the note, and the payee pays the bank's charges, plus the amount of the note."

Dr. Munro asked how this fitted in with the prospective plans of the Blue Shield. He added that he presumed that this plan did not apply to the income group that is affected by the Blue Shield. Dr. Ellison replied that the bank plan will supplement both the Blue Cross and the Blue Shield. He added that there are certain people to whom

the Blue Shield is not available and that the bank plan will serve such people.

In answer to further questioning on the part of Dr. Munro, Dr. Ellison reiterated his belief that the bank plan was complementary to the Blue Shield and not in competition with it.

Dr. Munro again emphasized the thought that, if the Society is going to play ball with a commercial organization that is obviously in the business for profit it should be clear whether or not the plan is in competition with the Blue Shield. At that point, the President observed that the plan has already been approved by the Council and that, therefore, this phase of the subject was not under discussion. Dr. Munro said that his purpose was to make clear to himself and to others certain phases of the subject that heretofore had been obscure.

Dr. George J. Connor, Essex North, asked what was the difference between this and the Morris Plan. Dr. Ellison replied that it was similar to the Morris Plan. Dr. Connor then observed that, if the doctor signs the note and the patient fails to come through, he, the doctor, is liable for the note. Dr. Ellison replied that this was the situation as he understood it.

Dr. Connor, in commenting on the statement coming from the bankers to the effect that most small loans were sought for medical purposes, said that, although such might be the reason given to the bankers by those seeking loans, the facts did not always bear this out. He spoke of two cases in his own experience wherein his bills were small and the loans sought from the Morris Plan were much more. In one instance the patient sought the additional money to finance a divorce, and in the other, to purchase an automobile.

At that point, the President said that the Massachusetts Dental Society was participating in this plan. He asked Dr. James C. McCann, president of the Massachusetts Medical Service, to discuss the relation between this plan and the Blue Shield. Dr. McCann replied as follows:

I am not qualified to do what you ask. There are certain impressions, however, that I might convey.

The first is that when the committee was working on a prepaid medical-care program, and when Dr. Bagnall was working on this program under the auspices of the Society, we were attempting to provide for the costs of medical care on a nonprofit basis. Yet we are faced with the fact that certain groups are approaching this problem on a profit basis. Whether commercial companies can accomplish more than we can remains to be seen.

There is unquestionably a call for an arrangement whereby those people who have seen fit not to participate in a prepayment program can accomplish this comfortable postpayment of their bills. Whether or not they participate is often up to the industry in which they work, and not up to themselves. This plan does offer them a way to handle it on a postpayment basis.

I might add that before Michigan undertook the prepayment program, they attempted a postpayment program, something of this character, on a nonprofit basis. It failed so definitely that they shifted to the prepayment basis.

The President at that point said:

Outside of the field of medicine he has been for many years one of the administrators of one of the largest universities in the United States. With such a record I think you will agree with me when I say that Dr. Roger I. Lee is eminently qualified to be the president of the American Medical Association.

The President asked Dr. Lee to stand so that all might see what he looked like. Dr. Lee arose and was greeted with loud applause.

Dr. Daniel B. Reardon, Norfolk South, asked the speaker if there is pending before Congress a bill establishing a public-health office in the Cabinet. Dr. Mongan replied in the affirmative. Dr. Reardon asked for the number of the bill. Dr. Mongan replied that he did not have the number at the moment but that he could get it. He added that the bill had been introduced by Representative Miller, of Nebraska, and that the latter is a doctor.

The President announced that Dr. Mongan's report called for no action.

Subcommittee Appointed to Meet With the Medical Advisory Committee of the Industrial Accident Board — Dr. Daniel J. Ellison, Middlesex North, chairman.

Dr. Ellison said that this subcommittee had no special report. He said that he had been appointed by Dr. Roger I. Lee, when the latter was president, a member of the general committee concerned with the conduct of the convention of the Associated Industrial Accident Boards and Commission of the United States and Canada. He added that this convention was held in Boston at the Statler Hotel in September, that it went off well and that he had enjoyed his part in it. He expressed his thanks to Dr. Lee for the assignment. (Dr. Ellison was chairman of the Reception Committee of the above event.)

Dr. Bagnall thanked Dr. Ellison for his report and called the Council's attention to an editorial and a communication from the Secretary's office that appeared in the *New England Journal of Medicine*, issue of September 28, 1944. He added that this material substantially reports the accomplishments of Dr. Ellison's committee. He urged the councilors to inform themselves on this matter.

He said that Mrs. Tousant had circularized the hospitals on the matter and that reprints of the editorial and the communication from the Secretary's Office will be sent to the chiefs-of-staff of all Massachusetts hospitals. He expressed the hope that the chiefs-of-staff will see to it that their respective members are informed with respect to these communications.

Subcommittee on Tax-Supported Medical Care — Dr. John J. Dumphy, Worcester, chairman.

The President announced that Dr. Dumphy was ill and that there would be no report from this subcommittee.

Subcommittee on Postpayment Medical Care (Bank Plan) — Dr. Daniel J. Ellison, Middlesex North, chairman.

In offering this report (Appendix No. 5), Dr. Ellison spoke as follows:

This report is presented without a meeting of the full committee having been held, and for this I sincerely apologize. Last August, Dr. Bagnall and I went to a meeting at the Parker House with a committee of the Massachusetts Bankers' Association, where Mr. McCarthy, vice-president of the National Shawmut Bank, presented this plan to the Massachusetts Bankers' Association. At that time he requested that nothing be said or done about the matter until he gave further notice of certain releases that he wanted to have made. The reason for that was that the outline or design of the brochures planned and the pamphlets and the wording of them was in process of being copyrighted, and he did not want some other organization to take this up through the publicity that might be given, and develop it prior to the receipt of the copyright. I have not heard from Mr. McCarthy, so I thought that it would be unwise to call doctors from all parts of the Commonwealth to a meeting where nothing definite could be accomplished. The meeting will, however, be held in the near future. I again apologize to the other members of the committee:

As you know, the spade work on this proposition has been ably done by our good president, Dr. Elmer S. Bagnall. The details of it have been presented at previous meetings. We are now concerned with the method of putting the plan into effect.

The original committee estimated that it would cost between \$500 and \$600 to put this over. Not one of us, and there were only three, had the courage to stand before the Council and ask for that sum of money. But it seems that miracles can happen, even for doctors. Mr. McCarthy got in touch with the American Bankers' Association, and was invited to meet with them in New York City, where they accepted this plan with open arms. They said that they would underwrite the entire expense of the publicity, and that they would design and draw up these brochures and pamphlets that are being passed around. So that the financial end of it is taken care of, not owing to the efforts of the committee, but to Mr. McCarthy's work.

Their plan is to start this proposition in Massachusetts. If it is successful, it will be developed in all other states of the Union. Payments will be made to the American Bankers' Association by the member banks of Massachusetts. Thus, the entire publicity will be under the care of the bankers. The doctors will be incidental in promoting this proposition.

The doctors will be visited in their offices or at such places as they wish by delegates appointed from the Association, and will be asked to join this plan. It will not be necessary for the doctors to go out among each other. However, your committee believes that it would be wise for the doctors in their district meetings to advertise the plan among each other.

The small-loans divisions of all banks in this state, as well as the small-loan companies, find that the second and third most frequent reasons given by people when applying for loans are for the payment of medical services. Obviously, a real need exists for this plan. Let it be understood that the rates charged for this plan are low, and easily explained. The charges are either added to or included in the doctor's fee.

There are two tables of rates. In the first, the charges connected with the loan are deducted, and in the second, the net plan, they are added to the note. A simple credit application is obtained, which the doctor or his secretary telephones to the bank. The facts are checked by the bank, and the doctor is notified when the note is approved. In due course the signed note is presented by the doctor to the bank for discount. To secure the doctor and the bank against loss, a reserve is set up for each account on the books at the bank in the doctor's name. The need for the reserve depends on the credit of the patient and on the doctor's practice. By agreement, the reserve may be in-

creased to cover marginal situations, although the usual reserve will be about 10 per cent.

This plan is open to all banks in Massachusetts, although it was started by the National Shawmut Bank. Some of the banks may adopt a different rate of reserve than others, and there may be a slight variation in the charge for this reserve.

This reserve, the 10 per cent having been taken out, is paid back to the doctor as payment on each account collected, unless the bank has some other charge against that particular physician, in which case the payment is credited against the other charge. As a result of the reserve feature, the term is shortened, so that the yield on the suggested rates compares closely with that of personal loans.

Whereas this has the appearance of collecting by the bank, it must be understood that the plan is in no way similar to the procedure of a collection agency. This plan is for current bills, not for the collection of bad bills. It is simply a method of making it easier for a man who eventually pays his bills to satisfy the legitimate claims of the physician, and to relieve the doctor of repeated monthly statements. It will take time for the plan to become the customary procedure. Over the years its use will expand.

Dr. George L. Schadt, Hampden, asked what was the basis on which the banks would consider a bill to be in the collection category. The President answered the question as follows:

The banks do not believe that it would be profitable for them if doctors took their bills that are five, six or seven years old, dumped them into a basket and gave them to the banks, but I am very sure that there would be no objection if some of these old accounts were turned over. Of course, the bank investigates the credit of each signee, and they will not accept the note unless they feel that there is a probability that the signee will go through. Furthermore the doctor, of course, should not endorse the note unless he thinks that his patient will probably stand behind it.

Dr. Schadt further inquired whether or not the doctor presents his bill to the bank on the completion of his work, whereupon it is paid by the bank, or whether he has to wait one, two or three months for such payment. Dr. Ellison replied that the arrangement can be made with the patient either during or after the illness.

Dr. Donald Munro, Suffolk, asked what the bank received. Dr. Ellison replied that, on amounts under \$100, the bank charges 50 cents a month.

Dr. Munro asked to whom the charge is directed. Dr. Ellison replied, "To the person who is being paid." He added that, if the doctor has a bill for \$100, he can deduct \$6, receiving \$94 in full payment from the bank. Dr. Munro replied that in essence this was a method whereby the doctor pays the bank to collect his bills. Dr. Ellison replied: "If the doctor wants to take out the charge, he is entitled to do so. If he does not, it is added to the amount of the face of the note, and the payee pays the bank's charges, plus the amount of the note."

Dr. Munro asked how this fitted in with the prospective plans of the Blue Shield. He added that he presumed that this plan did not apply to the income group that is affected by the Blue Shield. Dr. Ellison replied that the bank plan will supplement both the Blue Cross and the Blue Shield. He added that there are certain people to whom

the Blue Shield is not available and that the bank plan will serve such people.

In answer to further questioning on the part of Dr. Munro, Dr. Ellison reiterated his belief that the bank plan was complementary to the Blue Shield and not in competition with it.

Dr. Munro again emphasized the thought that, if the Society is going to play ball with a commercial organization that is obviously in the business for profit it should be clear whether or not the plan is in competition with the Blue Shield. At that point, the President observed that the plan has already been approved by the Council and that, therefore, this phase of the subject was not under discussion. Dr. Munro said that his purpose was to make clear to himself and to others certain phases of the subject that heretofore had been obscure.

Dr. George J. Connor, Essex North, asked what was the difference between this and the Morris Plan. Dr. Ellison replied that it was similar to the Morris Plan. Dr. Connor then observed that, if the doctor signs the note and the patient fails to come through, he, the doctor, is liable for the note. Dr. Ellison replied that this was the situation as he understood it.

Dr. Connor, in commenting on the statement coming from the bankers to the effect that most small loans were sought for medical purposes, said that, although such might be the reason given to the bankers by those seeking loans, the facts did not always bear this out. He spoke of two cases in his own experience wherein his bills were small and the loans sought from the Morris Plan were much more. In one instance the patient sought the additional money to finance a divorce, and in the other, to purchase an automobile.

At that point, the President said that the Massachusetts Dental Society was participating in this plan. He asked Dr. James C. McCann, president of the Massachusetts Medical Service, to discuss the relation between this plan and the Blue Shield. Dr. McCann replied as follows:

I am not qualified to do what you ask. There are certain impressions, however, that I might convey.

The first is that when the committee was working on a prepaid medical-care program, and when Dr. Bagnall was working on this program under the auspices of the Society, we were attempting to provide for the costs of medical care on a nonprofit basis. Yet we are faced with the fact that certain groups are approaching this problem on a profit basis. Whether commercial companies can accomplish more than we can remains to be seen.

There is unquestionably a call for an arrangement whereby those people who have seen fit not to participate in a prepayment program can accomplish this comfortable postpayment of their bills. Whether or not they participate is often up to the industry in which they work, and not up to themselves. This plan does offer them a way to handle it on a postpayment basis.

I might add that before Michigan undertook the prepayment program, they attempted a postpayment program, something of this character, on a nonprofit basis. It failed so definitely that they shifted to the prepayment basis.

The President at that point said:

I think that it must be apparent that a few of us have thought this thing through and have the right perspective on it. The committee, I am sure, will give further publicity to this matter. I understand that there is a plan in Springfield, initiated by the banks, that is operating very successfully. I have no direct information about that. There are also plans in other states, there being one in New Jersey and one in New York.

The head of the Advertising Department of the American Bankers' Association talked about this thing at the A.B.A. meeting a week or so ago, and he said that the bankers were very enthusiastic, and that they wanted the plan to be made nationwide. The Massachusetts program is a sort of pilot experiment, and the bankers think well enough of it so that they are willing to subsidize the plan.

A councilor asked who would be responsible in the event that a patient left an unpaid balance of 80 per cent. Dr. Ellison replied that the doctor would. He spoke of a man in his community who did a lot of work on venereal diseases. He added that it was the man's habit to have such patients obtain a loan from the Morris Plan Bank for \$50. Immediately on the failure of the patient to pay his regular installment to the bank, treatment was stopped. Dr. Ellison said that the doctor was driven to this by the fact that such people are notorious for not paying their bills.

Dr. Ellison moved the acceptance of the report. This motion was seconded by Dr. Richardson, and it was so ordered by vote of the Council.

(During the discussion of this matter, copies of a prospectus on the above matter had been passed among the councilors.)

Subcommittee Concerned with Prepayment Medical-Care Costs Insurance—Dr. James C. McCann, Worcester, chairman.

This report (Appendix No. 6) was offered by Dr. McCann. Dr. McCann moved that the Committee Concerned with Prepayment Medical-Care Costs Insurance, having completed its work, be discharged. This motion was seconded by Dr. Walter H. Pulsifer, Plymouth.

Dr. Allen G. Rice, Hampden, moved as an amendment that the original motion carry with it the thanks of the Council. This amendment being acceptable to the maker and seconder, it was declared by the President to be part of the original motion. It was so ordered by vote of the Council. (Dr. McCann was the recipient of loud applause as he left the platform.)

REPORTS OF SPECIAL COMMITTEES

Committee on Cancer—Dr. George A. Moore, Plymouth, chairman.

No report.

Committee on War Participation—Dr. Guy L. Richardson, Essex North, chairman.

Dr. Richardson reported as follows:

This year's work of the War Participation Committee had barely started when the report reached us of the death of Dr. William B. Breed, the first chairman of the com-

mittee. We had supposed his resignation had been sent in to lighten his efforts and to enable him to convalesce more quickly and that he would soon be back among us. Such was not to be the case, and our deliberations opened with the knowledge that the Council had lost a devoted and tireless worker.

It was apparent from the material Dr. Breed sent to me that he and his committee had done a prodigious amount of work. The records were carefully kept and catalogued and delivered to me in splendid shape.

So far as possible all projects undertaken or under discussion had been completed or decided. We were able to start afresh, and that was of particular help to Dr. Harold Giddings and myself, the two new members of the committee.

The first project that came to us was a request from the state office of the War Manpower Commission to assist them in drawing up a standard certificate form for a physician to sign whenever an applicant wished to change his job because of his health. The Commission thought that some doctors were too easily prevailed on by their patients to sign these certificates and that they were not careful to ascertain whether or not the old job really was detrimental to the applicant's health. Doctors too readily accepted their patients' statements about the health menace when the real reason for wanting to change jobs was to make more money or to work nearer home. As a result of this certificate abuse the work of the Commission in the war effort was being seriously interfered with. The following is an example of a case of apparent abuse: A dye worker presented a physician's certificate that his work was injurious to his health. Request to change employment was denied by the Commission. The worker then returned to the dye house and asked for his old job back. The employer refused because of the doctor's certificate stating that dye house work was injurious to that employee. The next day the worker returned with a statement from the same doctor to the effect that he had been completely cured and could safely resume his regular duties in the dye house.

The committee jumped into this project, believing it was what we were set up for. We advised a short certificate form and helped shorten it. If there is anything a physician hates to see pushed at him these days, it is a long questionnaire to answer and sign. We agreed to review the medical aspects of any doctor's certificate that the War Manpower Commission was uncertain about. Believing that the certificate abuse would be greatly lessened if doctors were fully informed of the harm caused by job jumping, space was given us in the August 3 issue of the *Journal* to depict the certificate form and to explain the whole matter.

It is gratifying here to reaffirm an earlier impression—that Massachusetts physicians will co-operate in any plan for the public good if the reason therefor is made plain to them. Thus far the committee has been asked to review not one of these new certificates. I should like to see that record maintained.

Let me quote from a letter to me under the date of September 18 and signed by Powell M. Cabot, state director of the War Manpower Commission: "In general, the opinion throughout the State is that this form has been of considerable value and has definitely corrected the situation which existed prior to its use."

The next appeal for aid came from the War Food Administration. Fats were scarce and were expected to become more so. Heavy cream prescriptions were being given out too freely by physicians. The purpose of the directive on heavy cream was thereby being defeated. The committee promptly assisted the War Food Administration to get the desired publicity. Through the local war-participation committees in all sections of the Commonwealth, we attempted to get full information to doctors and public as to the need for conservation of heavy cream, and to familiarize them with the opinions of the expert committees of the American Medical Association to the effect that heavy cream is rarely a necessity in medical treatment. We hoped this would lessen patients' applications for prescriptions and assist physicians in refusing to give them.

It has been estimated that the number of heavy-cream prescriptions coming in to the War Food Administration decreased more than 50 per cent after this publicity, and each succeeding week the decrease continues. The credit

for this remarkable showing belongs to Mr. John H. Sullivan, district supervisor of the War Food Administration, and his medical advisory committee, composed of some of our most respected physicians. They furnish the teeth for this act, and no amount of publicity in this instance is comparable to the effect of their decisions. It is a thankless job and gets them a lot of abuse. They are doing it with courage and fairness. I urge you to give them your support.

Another question brought before the War Participation Committee was the adequacy of hospital care for emergency cases in the largest cities of the Commonwealth — Boston, Springfield and Worcester. It was agreed that, in the smaller communities, no such problem existed. It was voted to send a letter to each of the major hospitals in those cities, asking how often in the last year it was necessary, for any reason, to refuse admission to an emergency case — either private or ward. These letters, forty-two in all, went out September 22, and already half the hospitals have replied. From a hasty reading of the answers, it appears that most of those hospitals never refuse admission of an emergency case. Some admitted having to turn away a few patients because of lack of beds or personnel. A complete report on this question will be made to the Council at a later date.

Dr. Richardson moved the acceptance of the report. This motion was seconded by Dr. Connor, and it was so ordered by vote of the Council.

Committee on Rehabilitation — Dr. William E. Browne, Suffolk, chairman.

Dr. Browne read into the record two letters. The first, which he had addressed to Dean A. Clark, Surgeon (R), United States Public Health Service, Physical Rehabilitation Section, Office of Vocational Rehabilitation, Washington, D. C., reads as follows:

Dear Dr. Clark:

I believe the date was April 26 of this year, I had the privilege as a member of the Boston Hospital Council of listening to your very worthwhile explanation of a program, not at that time completed, which had to do with rehabilitation.

You, no doubt, are well aware of some of the activities of the Massachusetts Medical Society. Perhaps when it was one hundred and fifty years old you read the late Harvey Cushing's paper concerning the Society and his paper was entitled "From Tallow Dip to Television." All during the years of its existence, as is the story with other state societies, its members have always tried to be of benefit and help to our citizens.

We have a committee of rehabilitation in the Massachusetts Medical Society. Pursuant to a communication from you dated February 5, 1944, our committee had a very pleasant dinner meeting with a representative of the Department of Rehabilitation of this Commonwealth acting under the direction of the Department of Education. Recently we received a query from the American Medical Association (a form query I assume), asking us what we had done and what we proposed to do in this matter of rehabilitation. Our reply was that twice since Wednesday, April 5, 1944, we had been in communication with the director of rehabilitation of the State, and each time had been informed, in substance, that committees in the various counties of the state were about to be set up, but up to now the Department of Rehabilitation in the state had not been ready to avail itself of any help which might be extended to it and which it really wanted from the physicians in the state and particularly the members of the Massachusetts Medical Society. On Monday, November 15, 1943, we communicated with the powers that be in Washington and asked whether or no it would be helpful to have two members from each of the district county medical societies in the state communicate with the Department of Rehabilitation for whatever assistance we might be in this matter of rehabilitation. We were informed that no definite program was at that time in operation.

Would you please consider this communication to you a personal one and in no sense going over the head of the director of rehabilitation in this state who is a very worth-

while individual. Busy though you may be, could you let our committee on rehabilitation know whether or not any state medical society in our country is at present functioning actively in any rehabilitation program approved by you and your department? Secondly, would you let me know if we are correct in assuming that we may not be of any service to the Department of Rehabilitation in our state or in the country as a whole until we are asked to be of assistance by those in charge of this program?

Sincerely yours,
William E. Browne

Dr. Clark's reply is as follows:

Dear Dr. Browne:

Thank you very much for your personal letter of August 30, which I found upon my return from a field trip.

The interest of the Rehabilitation Committee of the Massachusetts Medical Society in the expanded vocational rehabilitation program is very gratifying. There are a few facts about the development of this program which may be of interest to you.

You will recall that the Barden-LaFollette Act, Public Law 113 (78th Congress), was enacted by the Congress in July, 1943. The Office of Vocational Rehabilitation was established in the fall of last year and in January, 1944, the staff of the Physical Restoration Section was appointed by arrangement with the Surgeon General of the United States Public Health Service for the assignment of medical officers. The appointment of a national Professional Advisory Committee and the formulation of federal requirements and recommendations for physical restoration services in the state programs were the major activities of this section during the first portion of the year. These requirements and recommendations were considered at the meeting of the committee on March 3 and 4, 1944, and were issued as a section of the *Manual of Policies* to all state vocational rehabilitation agencies and state agencies for the blind on April 24, 1944.

The physical restoration aspects of the program constitute an entirely new activity for almost all the states and require considerable interpretation and assistance to state officials by the regional representatives and technical consultants of this office. The first installment of the physical restoration amendments to state plans, dealing with the administrative organization and qualifications for administrative personnel for the physical restoration unit, was due in this office on July 1, 1944. The second installment of the physical restoration amendments to state plans, dealing with the general criteria to be followed in the provision of physical restoration services, medical diagnosis, scope of physical restoration services, standards for physicians and other professional personnel, and rates of payment to hospitals will be due in this office on January 1, 1945. The complete operation of the physical restoration phases of the vocational rehabilitation program probably will be in effect in most states by July 1, 1945.

In the light of these facts, the inauguration of physical restoration services by state agencies will require some additional time before the necessary administrative staffs are recruited and policies established. In order to qualify for federal grants-in-aid the state agencies are urged to secure competent technical advice through advisory committees. It is recommended by the federal office that such committees be appointed by the state agencies after consultation with appropriate professional groups and that they include physicians representing the principal specialties of medicine concerned with rehabilitation and representatives of public health, hospital administration, nursing, medical social work, physical therapy and occupational therapy. The medical specialties particularly stressed are orthopedics, tuberculosis, psychiatry, ophthalmology, otology and so forth. On the basis of information thus far received practically all state medical societies have indicated their willingness to co-operate and in many instances have suggested physicians for the state professional advisory committees. I am sure the officials of the Massachusetts rehabilitation agencies are looking forward to the valuable assistance which can be rendered by your committee in conducting the physical restoration program, and I am, therefore, sending copies of this letter to Mr. Irwin Ristine, regional representative, Mr. Herbert A. Dallas, director, Division of Vocational Rehabilitation for Massachusetts,

and Mr. Arthur Sullivan, director, Massachusetts Division for the Blind.

I hope that I shall have an opportunity of discussing the rehabilitation program with you at some future date during a visit to Massachusetts.

Very truly yours,

DEAN A. CLARK, Surgeon (R), U.S.P.H.S.

Dr. Browne moved that the Council approve this correspondence. This motion was seconded by Dr. Hornor, and it was so ordered by vote of the Council.

Dr. Browne endeavored to impress the Council with the importance of keeping up to date on this matter, saying that some day this is going to be a big problem and that he did not want it said at some future time that the Government had tried to get medical societies to do the right thing and finally had to do it itself.

Dr. Browne moved that his report be accepted as a report of progress. This motion was seconded by Dr. Hornor, and it was so ordered by vote of the Council.

Committee on Postwar Loan Fund—Dr. George Leonard Schadt, Hampden, chairman.

Dr. Schadt spoke as follows:

The committee has no formal report at this time. It is merely a brief informal report to say that the committee, through its various members, is appearing before the different districts during the next month or two, and then early in November we will get the questionnaire out suggested by the Council at its last meeting. We hope that every member will return that questionnaire postcard promptly so that we may know how the Society as a whole feels on this plan.

The President expressed the thought that no action by the Council on the report was necessary.

Military Postgraduate Committee—Dr. W. Richard Ohler, Norfolk, chairman.

Dr. Ohler reported as follows:

This will be a very brief report. Since the annual meeting the work of the committee has progressed as usual, with no letup during the summer months. Since October, 1943, when the Massachusetts Medical Society committee joined forces with representatives from other state societies in New England, and with representatives from the American Medical Association, the College of Physicians and the College of Surgeons, to organize what is now known as the New England Committee for War-time Graduate Medical Meetings, two hundred and nine such meetings have been given in twenty-one Army, Navy and Coast Guard installations in the New England area by a group of one hundred and sixty-nine instructors.

As a mark of appreciation for the work done by the various instructors, the First Naval District tendered a dinner to all instructors throughout New England at the Chelsea Naval Hospital on September 25. Needless to state, the occasion was very much appreciated by all who have given of their time to make this program a success.

Since our last report, this committee has lost the services of Dr. William B. Breed. In this particular effort, as in any work or endeavor in which Dr. Breed had a part, we miss his wise counsel, his enthusiastic support and, beyond all else, his great friendliness and human understanding.

Dr. Ohler moved the acceptance of the report. This motion was seconded by Dr. Merrill C. Sos-

man, Suffolk, and it was so ordered by vote of the Council.

Medical Advisory Committee to Regional OPA—Dr. Joseph Garland, Suffolk, chairman.

Dr. Garland reported as follows:

The problem of determining extra ration allotments on certificates of patients' necessity continues to be a vexing one. Point values shift frequently and difficulties are often encountered in obtaining unrationed foods. Thus, with the individual still receiving $7\frac{1}{2}$ red points weekly, the point value of butter has jumped to 20 points per pound, and, although many types of meat are off the ration list, they cannot always be found on the counters, although in this respect it is worth mentioning that only 29 per cent of all the meat in the country at this time is rationed. Many persons, moreover, are still apparently unable or unwilling to adjust themselves to the use of fats and meats of low or no point value.

To these facts, and to the new regulation that local boards are allowed to issue extra points for diabetes and active tuberculosis only, may be attributed the increased rate at which applications are coming to the regional office—815 in the first twenty days of September. It seems apparent to the committee that many more certificates are being submitted than is justified on the basis of the facts in individual cases, which again brings up the problem of publicity and education for both the public and physicians. As the need for food rationing continues, and there seems to be no immediate prospect of its coming to an end, this education should be brought about by an increased reliance on local advisory committees—perhaps in most instances the local war-participation committees already in existence. Committees have been formed this summer in Scituate and Brockton, and others are scheduled for Lawrence, New Bedford, Springfield, Worcester and Pittsfield. The policy will be extended as the need arises.

Advisory committees are now functioning in Connecticut, New Hampshire and Maine, in addition to Rhode Island, which has helped somewhat in lightening the labors of the Massachusetts committee.

When new restrictions on the prescription of heavy cream were imposed on August 1, this committee was incorporated into a new and larger advisory committee to aid the War Food Administration.

Dr. Garland moved the acceptance of the report as one of progress. This motion was seconded by Dr. Richardson, and it was so ordered by vote of the Council.

The President solicited the support of the sub-committees that have or will be appointed under this program. He added that it was important to demonstrate the Society's capacity and willingness to participate in these emergency matters to the end that we may not later be criticized for holding out against or opposing any of the governmental program.

Committee on Medical Information Bureau—Dr. Walter G. Phippen, Essex South, chairman.

Dr. Phippen reported as follows:

This is simply a report of progress. The telephone has been installed in the room across the corridor from Dr. Tighe's office. We are in process of hiring an operator. We are holding a meeting on Wednesday afternoon, October 25, at 4:00 p.m., to which are invited representatives of all the hospitals in Greater Boston to discuss the technical operation of the Bureau, and we hope to have it in operation soon. It will be listed in the telephone directory under Massachusetts Medical Society, Clinical Information. Unfortunately the telephone company allows only two words so the word "Bureau" must be eliminated.

Dr. Phippen moved that the report be accepted as one of progress. This motion was seconded by Dr. Cheever, and it was so ordered by vote of the Council.

Committee on Postgraduate Instruction — Dr. W. Richard Ohler, Norfolk, chairman.

No report.

Committee on Physical Therapy — Dr. Arthur L. Watkins, Middlesex South, chairman.

The report, which was offered by Dr. Watkins, is as follows:

This committee has functioned chiefly with the aim of increasing the use of physical therapy by general practitioners. To accomplish this purpose a paper discussing physical therapy in general practice has been published in the *Journal* and monthly symposiums have been given in service hospitals in connection with the wartime graduate medical meetings.

Dr. Watkins moved the acceptance of the report as one of progress. This motion was seconded by Dr. Hornor, and it was so ordered by vote of the Council.

Committee on Expert Testimony — Dr. Frank R. Ober, Suffolk, chairman.

This report (Appendix No. 7) was offered by Dr. Ober.

Dr. Ober moved the acceptance of the report. This motion was seconded by Dr. Phippen, and it was so ordered by vote of the Council.

Dr. Ober moved the adoption of the following recommendations contained in the report:

1. That a standing committee of five or more, to be called the Committee on Medicolegal Problems, be appointed by the president.
2. That the by-laws of the Massachusetts Medical Society be amended to provide for such a body.

This motion was seconded by Dr. Schadt.

Dr. Rice expressed the wish to hear some debate concerning the necessity of establishing another standing committee. He added that the Committee on Ethics and Discipline had had only two such cases and that this committee is not overburdened.

Dr. Reginald Fitz asked if these recommendations did not imply a change in the by-laws and, if that was so, if some special action was not required.

The President replied that such was embodied in the second recommendation.

Dr. Carl Bearse, Norfolk, said that the matter of creating a standing committee deserved serious consideration. He added that questions concerning medical expert testimony are now being taken up by many other state medical societies. He stated that Michigan and Connecticut are working on a plan at the present time and that California has a plan, which goes in for education along these lines, there being a panel of physicians who talk to lawyers on the medical aspect of expert testimony. He said that he had noted recently that there were 4000

malpractice suits in the country each year. He added that this problem was coming up constantly and that it was his opinion that the problem could best be met by the creation of a standing committee.

Dr. Hornor asked:

Is it the intention that this committee will serve to offer a panel, or the equivalent of a panel, to judges so that the judges will know whether the man who is testifying, be he a neurologist, laryngologist or orthopedist, really knows something about his specialty? It seems to me that what we need is prevention of poor testimony rather than the disciplining of people who have testified poorly.

I think that we need to help the judges and the courts to know whom they want to testify before them. And if that would be a part of the work of this committee, I should be much in favor of it.

Dr. Ober, in reply to Dr. Hornor, said that his committee did not consider that it was its function to discuss how this should be done. He continued as follows:

We thought that that should be left to a standing committee, and that that standing committee should not proceed overnight to try to reform the whole procedure of expert testimony. Your scheme, however, is a part of it.

Now there may be some objection to the panel system, and perhaps we should not get into an argument about that now. That should come up as a report of the standing committee. We hope to submit a by-law that will cover the duties of the standing committee, and that by-law should be discussed when presented. I do not believe that this is the day to present the by-law. This committee should be instructed to present a by-law on the functions of such a standing committee, similar to the by-laws that describe the functions of other standing committees.

There are a great many matters that have to be considered in this thing. First, there is the bad medical witness, and there is the court testifier who goes around testifying as an expert in all sorts of things. There is the question of rules of procedure in the courts, and the question of subpoenas, having a constable come into your office and serve you with a subpoena as an ordinary witness, and you get down there to the court and find you are going to be qualified as an expert witness, and that does not seem to be quite fair to some of us. Then there is the question of one doctor testifying against another. So there are a great many aspects of this thing that cannot be settled by the Committee on Ethics and Discipline.

The Committee on Ethics and Discipline is a court, as I see it, to settle many problems of this nature. The Committee on Medical Defense, of which Dr. Allen is chairman, has, of course, headed off a great many suits for malpractice, but we believe, in addition, that there is an educational aspect. Every doctor should be informed concerning what constitutes malpractice and concerning proper conduct toward his patient, so that he does not interfere with the code of ethics of the American Medical Association and the code that we have adopted and so that he will not tell some patient, "Well, so-and-so just treated you rottenly." We should like to stop all that.

We believe that such a committee has a special job to do, and that this legal thing is in its infancy. It has not been changed in the last five hundred years, and with a standing committee that has a constant function, — and the standing committee should be changed so that new blood would be instilled into it every so often, — we think that the Society would get farther in straightening out some of the bad expert testimony that is going on.

The Briggs Law has done a tremendous amount of good to straighten out testimony in criminal cases in which the problem of insanity arises, and it has cut out a lot of poor expert testimony. Some of you, perhaps many of you, will remember what happened in the Thaw case a great many years ago. We do not have that in Massachusetts.

Dr. Schadt spoke as a former chairman of the special committee. In replying to Dr. Hornor's

question, he said that he and his committee had in mind the question of setting up a panel at that time. He said that he had discussed this with certain representatives of the Massachusetts Bar Association and that they were sympathetic. He added that the importance of this committee is great and that a committee of this kind could do great work.

Dr. Munro spoke as follows:

There is no question but that this is a tremendously important problem. I should like to emphasize what Dr. Horner has said and what Dr. Schadt has said, and what Dr. Ober has also emphasized. This problem is so intimately bound up with the law of testimony and the power of the courts to declare a man expert or not expert on what seems to the medical profession to be inadequate evidence, that I think that the Society should consider very carefully the advisability of obtaining active co-operation from the Massachusetts Bar Association before committing itself to the creation of a standing committee.

Now I do not mean that a standing committee should not be created. I think a standing committee should eventually be created, just as Dr. Ober suggests, but to create a standing committee means that certain rules, procedures and duties must be outlined, also as he requests.

It does not seem wise to me for the Society to go off the deep end at this moment, and create such an important committee, until it knows very well what the rules and procedures and functions of that committee are going to be, and those cannot be known, I believe, until the active co-operation of the Massachusetts Bar Association is obtained.

I should think that it would be very much more to the purpose to have this thing handled during this formative period by the special committee, and then when all organizations and the Massachusetts Bar Association have co-operated, as I am sure they will, a standing committee could be formed with rules and duties and methods of procedure that would fit the case as it actually exists, and not as it was thought to exist.

Dr. Charles C. Lund, Suffolk, spoke as follows:

The question before the house is whether or not we should create a standing committee.

It seems to me that Dr. Ober's report has not given us quite enough information to make a decision at this time. To decide whether we should have a permanent committee rather than a temporary one, I think we should know from Dr. Ober, first, what he has done, second, what his problems are and, third, why those problems cannot be solved by the present committee. I probably should be in favor of a standing committee because I know that this subject is important and because I want to see everything done by the Society that can be done to keep medical testimony on the highest plane.

Dr. Cheever arose to say that he thought he might clarify some of the issues. He spoke as follows:

Almost everything that has been said was brought up in our committee, and we considered it very carefully, and our committee is not at all convinced or sure of how much we can accomplish.

Now there are a number of interesting things to remember. Obviously, there are three major parties to this situation. There is the judiciary; there are the lawyers; and there are the doctors. The judiciary, of course, constitutes the entire organization of the courts. You will be perhaps rather surprised to know that there are ten thousand practicing lawyers in the state but that only fifteen hundred of them belong to the Massachusetts Bar Association. Only two thousand of them belong to the Boston Bar Association. It is perfectly evident, then, that eight thousand of the ten thousand practicing lawyers in Massachusetts are outside the jurisdiction of any agreement that those two bar associations might make. That is a very unfortunate situation.

Dr. Horner's question about the panel was something that we considered carefully and thought that we could not possibly decide. It seems to me almost impossible that a panel of the members of the Massachusetts Medical Society could be arranged and constituted and accepted by the judiciary and accepted by the lawyers in connection with these cases.

We consulted with the secretaries of the bar associations and learned an interesting fact: there is a movement on foot to integrate both these bar associations and all the lawyers in the state into a single association. And if that can be done, it is obvious, I should suppose, that their rulings and decisions would have to be observed by all the lawyers of the Commonwealth. When that is done, we could proceed with more certainty of some success.

There is another thing that I should like to emphasize in connection with what Dr. Rice said, and that is that it would seem, having read a little editorial note in the *Journal* some weeks ago, as though it were not generally known how adequately the Committee on Ethics and Discipline in the past has handled this situation.

We have always had—I can personally testify for twenty years—a Committee on Ethics and Discipline that has been glad to receive complaints about unimpaired medical expert testimony, that has considered those cases and that, in a good many instances, has disciplined the offender even to the extent of securing his resignation from the Society. So that if you will read the statement about the Minnesota Bar Association, you will find that what they are congratulating themselves about is an arrangement precisely similar to that, so far as I can see, that has always obtained here. So we are not so very far behind.

It did seem to this committee, of which I am a member, that the Society as a whole is sufficiently informed about the functioning of the Committee on Ethics and Discipline in these cases. Of course, we can inform it, but it seemed to us that the creation of a new standing committee would serve as a means of so informing the Society, and bringing the matter more acutely into the foreground. And it was our belief and intention that this new committee would organize the work, would sift the cases as the evidence was presented, and present to the Committee on Ethics and Discipline for final adjudication the issues involving the question of disciplining an offender. That is about as far as we were able to go.

Dr. Browne observed that the litigant in dealing with the subject must not be forgotten, for without him there would be no case. He thought it would be questionable whether or not a panel would work out. He said that it was discretionary with the judge whether or not the individual doctor could qualify as an expert. He added that judges exercise this discretionary power in various ways. Dr. Browne expressed himself as feeling that it might be wise to refer this matter to the Executive Committee. Reverting to the matter of a panel, he thought such might be a valuable thing if one of the panel were to listen to medical testimony offered in court. He finally concluded with the thought that he was quite sure that a standing committee will ultimately be a necessary and helpful thing for the Society. He questioned, however, the wisdom of doing this without further deliberation.

Dr. Schadt was recognized by the chair. He referred to the remarks made by Dr. Rice and said that the work of this committee should be to educate doctors, both members and nonmembers of the Society, so that they may become good witnesses to the end that they may never have cause to appear before the Committee on Ethics and Discipline. He concluded by saying that he thought

that this would be a valuable committee for the society.

Dr. Stratton expressed himself as favoring such committee, particularly its educational function. He did not, however, think that a standing committee should be created until such time as the special committee brought into the Council a definite program with which the Massachusetts Bar Association concurs. He added that, when and if such a situation was realized, the Committee on Ethics and Discipline would be relieved of a tremendous amount of work usually associated with assembling the facts in any given case.

Dr. Ober expressed the thought that the Society was not going to get anything out of the lawyers until it had done something itself. He spoke as follows:

Under the prevailing system of trial by jury or before a judge the conduct of a lawsuit is a bilateral contest to see which side will win. In the procedure of producing direct testimony, everything favorable to the client is presented, and on cross-examination everything may be done to discredit or destroy that testimony. Too often the debate is emotionalized and dramatized by one side or the other, in order to influence the jury. Therefore, it would seem in the interests of justice that some other method of considering expert testimony might be worked out which would be superior to our present system.

He concluded that this would be one of the main functions of this standing committee.

At that point the recommendations of the committee were restated. Then, they were adopted by a standing vote of the Council.

The Secretary arose to say that the adoption of the recommendations did not constitute a formal amendment to the by-laws and that, if such an amendment were to be acted on at the annual meeting in 1945, it must be offered at this meeting or at the meeting in February.

The President asked if anyone was prepared to introduce a formal amendment.

Dr. Bearse moved that Chapter VII of the by-laws be amended by adding Section 16, to read as follows:

The Committee on Medicolegal Problems shall consist of five fellows. It may appoint auxiliary members. It shall concern itself with medicolegal problems.

This motion was seconded by Dr. Lester M. Felton, Worcester.

Dr. William A. R. Chapin, Hampden, moved that this matter be laid on the table. He said that he had made this motion because he thought standing committees were something to think about and because he did not believe that amendments to the by-laws were done orderly when devised in two minutes. Dr. Chapin's motion was seconded by Dr. Munro, and it was so ordered by vote of the Council.

Committee on Automobile Insurance Claims — Dr. Henry C. Marble, Suffolk, chairman.

In connection with the above committee, the President made the following statement:

The question arises whether or not to continue this committee. The committee has made no report, and it is the opinion of the President and the Secretary that a committee that makes no reports should not be carried on the rolls year after year. If there is no objection from the Council, this committee will be declared discharged, with thanks, because they did a good piece of work in organizing a plan for the direct payment to physicians by a gentleman's agreement with the insurance companies.

Do I hear any objection?

There was no response.

Committee to Study the Practice of Medicine by Unregistered Persons — Dr. Richard Dutton, Middlesex East, chairman.

Dr. Dutton said his committee had no report. He moved that the committee be discharged; the President added "with thanks," he being mindful of the applause with which this committee's report had been received several years previously. This motion was seconded by Dr. Conley, and it was so ordered by vote of the Council.

Committee to Meet with the Massachusetts Hospital Association — Dr. Walter G. Phippen, Essex South, chairman.

No report.

Committee on Maternal Welfare — Dr. Raymond S. Titus, Norfolk, chairman.

No report.

APPOINTMENTS

The President made the following nominations:

Auditing Committee:

Dr. Z. William Colson, Essex North, chairman.
Dr. David G. Cogan, Middlesex South.

To the Council:

Dr. Matthew J. Bachulus, Hampden, replacing Dr. Edward A. Knowlton, resigned.
Dr. Joseph A. Daley, Middlesex South, replacing Dr. John J. Cochran, deceased.
Dr. Kenneth J. Tillotson, Middlesex South, replacing Dr. Sumner H. Remick, a member *ex officio*.
Dr. Abraham Myerson, Norfolk, replacing Dr. Roy J. Heffernan, a member *ex officio*.
Dr. James J. Regan, Suffolk, replacing Dr. Reginald Fitz, a member *ex officio*.
Dr. John Homans, Suffolk (this district was entitled to one more councilor).
Dr. Theodore L. Story, Worcester, replacing Dr. Roy J. Ward, a member *ex officio*.
Dr. W. Richard Ohler, Norfolk, replacing Dr. Edward L. Kickham, deceased.

To the Committee on Public Health:

Dr. Conrad Wesselhoeft, replacing Dr. Roger I. Lee, resigned.

To the Committee on Postgraduate Instruction:

Dr. W. Richard Ohler, replacing Dr. Reginald Fitz as chairman.

To the Committee on Maternal Welfare:

Dr. Raymond S. Titus, chairman, replacing Dr. Louis E. Phaneuf, resigned.
Dr. Benjamin deF. Lambert.
Dr. Ralph E. Cole.

To the Committee on Postpayment Medical Care:

Dr. Daniel B. Reardon, replacing Dr. Walter L. Sargent, resigned.

To the Medical Advisory Committee to Regional OPA:

Dr. Loring Grimes.

To the Committee on Nominations:

Dr. Harry F. Byrnes, alternate member from Hampden District, replacing Dr. Edward A. Knowlton, resigned.

To the Board of Censors, Norfolk District:

Dr. H. Allan Novack, replacing Dr. Saul Berman, deceased.

Representative to the Massachusetts Central Health Council:

Dr. James W. Bunce, Berkshire, replacing Dr. Robert J. Carpenter, resigned.

Voting Member in Massachusetts Hospital Service, Incorporated:

Dr. Albert A. Hornor, replacing Dr. William B. Breed, deceased.

Representative on the Massachusetts Nursing Council for War Service:

Dr. David D. Scannell.

The President asked if there were any nominations from the floor. There being no response, Dr. Chapin moved the approval of the nominations. This motion was seconded by Dr. John B. Hall, Norfolk, and it was so ordered by vote of the Council.

NEW BUSINESS

The President read the obituaries of three former councilors.

DR. WILLIAM B. BREED, of Newton, died August 21, 1944. He was in his fifty-second year.

Dr. Breed received his degree from Harvard Medical School in 1920. He had been a member of the Council since June, 1929, and nominating councilor since 1939. At the time of his death he was a member of the Committee on Publications, having been appointed to that committee in February, 1940, and a voting member in Massachusetts Hospital Service, Incorporated. He was a member of the Board of Censors of Suffolk District from 1933 to 1937 and was supervising censor from 1937 to 1938. He was formerly chairman of the Committee on War Participation and a member of the Committee on Prepayment Medical-Care Costs Insurance and the Committee on Legislation. He was associate editor of the *Journal* from 1923 to 1937 and a member of its editorial staff from 1937 to 1942.

He had been secretary-treasurer of the National Committee for Wartime Graduate Medical Meetings since its organization in the summer of 1943.

Dr. Breed was a staff member at the Massachusetts General Hospital and an associate in medicine at Harvard Medical School. He was also a member of the American Medical Association, the American College of Physicians, the New England Heart Association and the American Clinical and Climatological Society.

His widow and three children survive.

DR. EDWARD L. KICKHAM, of Brookline, died August 10, 1944. He was in his forty-ninth year.

Dr. Kickham received his degree from Tufts College Medical School in 1923. He has been a member of the Council since 1937 and, at the time of his death, was a member of the Massachusetts Committee of the Procurement and Assignment Service. He was a member of the Board of Censors of Norfolk District from 1936 to 1939 and was supervising censor from 1939 to 1940.

He was a member of the obstetric and gynecologic staffs of the Carney Hospital and St. Elizabeth's Hospital, having been associated with the former since 1924 and with the latter since 1930. He had been instructor in gynecology at Tufts College Medical School since 1930.

Dr. Kickham was a fellow of the American College of Surgeons and the New England Obstetrical and Gynecological Society and a member of the American Medical Association, the American Board of Obstetrics and Gynecology and the Boston Obstetrical Society. He was treasurer of St. Luke's Guild of Boston.

His widow, two brothers and a sister survive.

DR. CHARLES A. SPARROW, of Worcester, died September 20, 1944. He was in his sixty-first year.

Dr. Sparrow was born in Marion and graduated from Amherst College in 1906, receiving his degree from Harvard Medical School in 1909. He had been a member of the Council since 1938. He was a member of the Committee on Public Relations from 1939 to 1943. He was an associate editor of the *Worcester Medical News*, a publication of the Worcester District Medical Society, as well as a past president of that society.

He was appointed to the staff of the Memorial Hospital in 1916 and in 1925 became head of the Pediatric Clinic there.

Dr. Sparrow perfected, as chief of the Medical Division of the Massachusetts Committee on Public Safety in Worcester, arrangements for the work of doctors, nurses and ambulances in case of enemy air activity.

He was a member of the American Academy of Pediatrics and of the New England Pediatric Society.

His widow, a son, a daughter and a sister survive.

The President asked the councilors to stand for one minute in silent tribute to these men.

The Secretary read the following excerpt from Chapter V, Section 1, of the by-laws:

The censors of the several district societies shall meet for the examination of applicants semiannually on the first Thursday in May and on the first Thursday in December.

He referred to the Council a membership certificate that had come from a district medical society in which the censors' examination had been held on October 6, 1943. He spoke of having written the district society and of having received a reply to the effect that the doctors in the district were extremely busy. Dr. William D. Kinney, Barnstable, said that he had been present at the May meeting when this examination had been started and that, owing to an emergency, the examination had to be discontinued and was not completed until October. Dr. Kinney moved that this candidate be admitted to the privileges of membership in the Massachusetts Medical Society. This motion was seconded by Dr. Henry W. Godfrey, Middlesex South, who expressed it as his feeling that this candidate, having started his examination at the proper time, should be admitted as of that date. It was so ordered by vote of the Council.

Dr. Allen G. Rice, Hampden, asked who sets the hour of the Council meetings. The President referred this question to the Secretary, who replied that the Council itself sets the hour of its meetings.

Dr. Rice pointed out how difficult it was for councilors from Springfield and points farther west to arrive on time for a 10:00 o'clock meeting. He said that, as it is now, such councilors must leave Pittsfield around 5:00 o'clock in the morning and Springfield at 6:45. He added that, if the hour of meeting were changed to 10:30 a.m., councilors could leave Springfield at 8:00 a.m. and arrive at the meeting on time. Dr. Rice made a motion to

that effect. This motion was seconded by Dr. William Dameshek, Norfolk, and it was so ordered by vote of the Council.

Dr. Dameshek moved that the Council set up a committee for the consideration of transfusions and blood grouping. This motion was seconded by Dr. Hornor.

In support of this motion, Dr. Dameshek spoke as follows:

I think all of us will agree that transfusions and blood grouping technics have come to the foreground a great deal in recent years. Furthermore, there has been the great expansion of blood banking, the Rh factor has been discovered and so forth. The number of transfusions has increased, and a great many reactions, sometimes fatal, have occurred. I happen to have seen a number of them in the past several years in the various parts of the Commonwealth. So I am beginning to believe more and more that there should be a committee of the Society to consider transfusions, standardization of the methods, the training of technical help doing the transfusions, the various agglutination tests, the Rh factor, transfusion reactions and so forth. This committee could gather information, it seems to me, of great importance to the members of the Massachusetts Medical Society, and could perhaps standardize procedures in various hospitals. I think that it is important for the Massachusetts Medical Society to do this first, before the Massachusetts Department of Public Health takes it over.

He said that it was his idea that this committee should be appointed by the President and that he was willing to leave the number of members to serve on it to the same authority.

Dr. Schadt asked whether such a committee would set up rules and regulations for community hospitals, private hospitals, private laboratories and physicians. Dr. Dameshek said that he was in the process of writing a letter to the editor of the *Journal* and that he would take up Dr. Schadt's question in that letter. He added, however, that he did not have it in mind that this committee should supervise the business of transfusions in hospitals and laboratories but rather that it should gather material and data on this subject and disseminate the information so obtained.

He went on to say that a great many blood groupings have been done with faulty serum, that a great many blood groupings are being done by incompetent personnel, that there are a great many reactions due to incompatibility that has not been properly checked, that the patient has not been watched properly during the administration of the first 50 to 100 cc., that too many transfusions of whole blood are now being given, that at times the typing and cross-matching procedures are not properly checked and that whole blood is frequently given while the patient is under a general or spinal anesthetic, the patient under such circumstances not having the full possession of his senses or his sensibilities. He expressed the thought that the standardization of the whole procedure might well be a function of the committee.

Dr. Lund said that he did not see how this committee could be of particular benefit or why a com-

mittee should be set up in this and not in other fields. He concluded by saying that it seemed to him that the answer to Dr. Dameshek's problem was for him to do a little study, write a paper and publish it in the *Journal*.

Dr. Hornor said that, when he seconded this motion, he visualized that there were many members of the Massachusetts Medical Society who were capable of gathering and sifting this information and disseminating it for the benefit of the rest. He said that the Committee on Maternal Welfare was a precedent for the action proposed.

The motion to establish such a committee was defeated by vote of the Council.

Dr. Alexander A. Levi, Middlesex South, was recognized by the chair. He read Section 2(b), of Chapter V, of the by-laws as follows:

The secretary of a district society shall receive an application from a graduate of a discontinued medical school, a foreign medical school or any medical school not approved by the Council only when:

The applicant has possessed a license to practice medicine in the United States or its territories for at least five years. . . .

He offered as an amendment to this section the following:

The applicant has possessed a license to practice medicine in the United States or its territories for at least five years, termination of the elapsed time to be based on the date of the next censors' meeting. . . .

This amendment was seconded by Dr. Hyman Morrison, Norfolk.

Dr. Levi went on to say that, under the present by-law, the applicant covered by Section 2 (b), of Chapter V, might actually have been in practice five and a half years before he became eligible to apply for membership. He said that he would like to see this situation changed so that the five years would be calculated as running from the time of licensure to the date of the censors' examination. He added that if his amendment prevailed an applicant could apply in the regular manner on or before September 15 provided his waiting period of five years would be over before the censors' examination was scheduled to take place in the following December.

The Secretary said he knew the situation that Dr. Levi had in mind to change. He felt, however, that the language of the amendment, as submitted, could be improved on so that its meaning would be clearer and unmistakable.

On a vote by the Council, the motion to amend the by-laws was lost.

Dr. Chapin was recognized by the chair. He made the following motion:

That the President of the Massachusetts Medical Society be instructed to use such means as he sees fit to investigate and report to the next meeting of the Executive Committee the question of the young returned medical officer assigned to duty in the military hospital versus the medical officer already established there but suitable for overseas service.

This motion was seconded by Dr. Conley.

In supporting his motion, Dr. Chapin said he had written a letter to the Secretary on this matter. He spoke of two young doctors who had returned from overseas and who had been assigned to a base hospital on limited service. He complained that these young men are not given the type of work they are trained to do. He added that the Commanding Officer of this hospital has an excellent setup but that the officers he has trained might well be suitable for overseas service, which would permit more advantageous placement of returned officers.

Dr. Lund thought it would be embarrassing for the Society to make any move in the way of asking the Army to look into the special cases of young men who are not getting the kind of work they like. Dr. Chapin said that what he desired was that these returned officers be used to some purpose and that they be made to feel that they are doing good medicine again.

At that point in the discussion, the President said that he would be very much confused about his duties as outlined in this motion. He said that he was a little in doubt how and where he should proceed to get the information for the Council. He added, however, that it was the President's duty to do what the Council asks him to do.

On a vote by the Council, the motion was lost.

Dr. Hornor moved that the Council adjourn. This motion was seconded by Dr. Lund, and it was so ordered by vote of the Council.

The President declared the Council adjourned at 2:00 p.m.

MICHAEL A. TIGHE, *Secretary*

APPENDIX NO. 2

REPORT OF THE EXECUTIVE COMMITTEE OF THE COUNCIL

The Executive Committee, in the name of the Massachusetts Medical Society, endorsed the Fifth War Loan Drive and referred a telegram from Dr. Olin West, secretary of the American Medical Association, concerning it to the Society's Committee on Finance.

A question arose in the Committee as to the legality of the Council's action in May, 1944, in adopting one of the recommendations contained in the report of the Committee on Medical Information Bureau. This recommendation had to do with an appropriation of \$2500, which was granted by the Council for the use of the committee. It was contended that the recommendation should have been first submitted to the Committee on Finance; failing in this, the Council should have made the appropriation contingent on its approval by this committee. The Executive Committee, taking notice of the general demand in the Society for the prosecution of the work of the Committee on Medical Information Bureau, instructed the President and Secretary to examine this situation. In the event that the appropriation had been improperly made, the President was urged to exercise his emergency powers so as to make this money available. Subsequently, each member of the Executive Committee was in receipt of an opinion on this matter written by the President. In substance this opinion is to the effect that there is inherent in several sections of the by-laws manifest evidence that it is the intention to have the Committee on Finance scrutinize any proposals for the expenditure of monies which are extraordinary or other than routine. The opinion goes on to say that there is also precedent for the appropriation of monies directly by the Council but this has been contingent on the appropriations approval by the Committee on Finance. The President has exercised his emergency powers and this money has been made available to the Committee on Medical Information Bureau.

The committee responded to a letter from Mr. Powell M. Cabot, Massachusetts director of the War Manpower Commission, asking that the Society set up machinery similar to that established for the purpose of aiding the Massachusetts OPA regarding rationing. This matter was referred to the War Participation Committee with instructions to co-operate with the Massachusetts War Manpower Commission. (The War Participation Committee will report on this matter later in this meeting.)

The Committee gave consideration to two additional communications, one from the Deputy Surgeon General of the United States Army and the other from the chief of the Procurement Division. They treat of the same subject and concern a change in policy in the office of the Surgeon General with regard to the commissioning of graduates of Middlesex University School of Medicine. I quote the pertinent part of the letter received from Deputy Surgeon General George F. Lull:

It is true that last December we stopped taking graduates of this institution [Middlesex] into the armed services. However, a few weeks ago we were approached by the dean of the school regarding seventy-five or eighty graduates of last year who had completed internships in accredited hospitals and who had been licensed to practice in Massachusetts. We told the dean that we would take these people, provided they were physically and otherwise qualified. You will see that the new rule can only apply to recent graduates, as they must have had accredited

internships, and those who have failed to pass the State Board will not be accepted.

The letter from Lieutenant Colonel Mark C. Elworthy, chief of the Procurement Division, concerns itself with the method by which graduates of Middlesex University School of Medicine, seeking commissions in the Army, will be processed in the future. This is as follows:

(1) Such a graduate must have a license to practice medicine in a state or territory and supply in proof of this a photostatic copy of his license.

(2) He must present evidence of completion of the four-year regular medical course and the possession of an M.D. degree: this evidence must be in the form of a letter from the dean of Middlesex University School of Medicine, testifying to applicant's completion of the four-year regular medical course and the possession of an M.D. degree.

(3) He must have had one year of rotating internship: in testimony thereof he must present a letter from the superintendent of a hospital approved for internship testifying to the fact that applicant completed at least one year of rotating internship. (An internship of nine months under the 9-9-9 program does not fulfill this requirement and is not acceptable.)

(4) He must have membership in a county or district medical society and present a photostatic copy of his current membership certificate or a certificate of an Army officer on active duty that he has personally examined such certificate and that it is satisfactory.

The last requirement may be waived if the applicant is in private practice and if he receives letters from three practicing physicians, graduates of approved schools and members of the district medical society where the applicant resides, testifying as to the applicant's ethical practice of medicine and professional qualifications. In lieu of this latter, the applicant may submit a letter from the secretary of the district medical society along the same lines. (The forms which these letters shall take are prescribed.)

In the event that the applicant is a graduate of Middlesex University School of Medicine and is in the process of serving an internship, in addition to the foregoing he must supply a letter signed by the chairman of the internship committee, by the superintendent of the hospital, by the chief of staff, by the chief of the medical staff and by the chief of the surgical staff. In no instance shall this letter be signed by less than three of such officers. (The form of the letter is prescribed.) This same regulation is in force for those graduates of Middlesex University School of Medicine who are hospital residents.

The Administrator of Veterans Affairs has advised that at this time only graduates of approved medical schools are acceptable for duty with the Veterans Administration Facilities. Therefore, physicians who are graduates of unapproved or substandard schools, including the Middlesex University School of Medicine, and who are physically qualified for duty only with the Veterans Administration Facilities, will not be processed. Any request to process such physicians will be returned to the Procurement Division with appropriate comments.

The Executive Committee has approved a plan submitted by the Red Cross for the training of volunteer nurse's aides in the treatment of infantile-paralysis patients in the noncommunicable stage of the disease. This matter was submitted to and approved by the Committee on Public Health of the Society.

The Committee reviewed the report of the Committee on Public Relations and approved the recommendations contained therein. (The Committee on Public Relations will report on this matter later in this meeting.)

The Executive Committee approved of certain ad interim appointments made by the President. (These appointments will be offered later in the meeting.)

MICHAEL A. TIGHE, Secretary

APPENDIX NO. 3

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations held a meeting at the Harvard Club, Boston, on July 26. President Elmer S. Bagnall, President-elect Reginald Fitz, Secretary Michael A.

Tighe and representatives from ten districts attended. In addition, there were present, at the invitation of President Bagnall, Dr. Hugh F. Hare, president of the New England Roentgenological Society, Dr. Charles W. Blackett, chairman of the Executive Committee of that society, Dr. Merrill C. Sosman, past president of that society, Mr. Cahalane, executive director of the Blue Cross, Mr. Walter Amesbury, a director of the Blue Cross and administrator of the Waltham Hospital, and Dr. George A. MacIver, president of the Massachusetts Hospital Association.

The first business of the meeting was the consideration of the inclusion of payment for x-ray examination by the Blue Cross. After presentation by President Bagnall of the action of the House of Delegates of the American Medical Association and the House of Delegates of the American Hospital Association on this question there was free discussion. Each of the guests representing the Blue Cross and the New England Society of Roentgenologists spoke on the question. The general discussion was frank and open, and there was a clear picture in the minds of the committee when the guests left. When the discussion was ended, President-elect Reginald Fitz made the following motions:

(1) The Committee on Public Relations of the Massachusetts Medical Society does not now approve the proposed plan of Blue Cross to pay \$15 toward the costs of x-ray in hospitals.

(2) Discussion by the Massachusetts Hospital Service, Massachusetts Hospital Association, New England Roentgenological Society and Committee of the Massachusetts Medical Society to meet with the Massachusetts Hospital Association — Dr. Walter Phippen, Chairman — should be continued.

This motion was adopted by vote of the Committee.

The next business before the committee was consideration of the report of the subcommittee appointed to look into the possibility of better publicity for the Massachusetts Medical Society. A progress report was presented, the most important feature of which is that the Connecticut Medical Society has instituted an elaborate plan for publicity, which the committee is going to investigate and report on later.

Finally, the progress report of the Committee to Meet with the State Advisory Council of the Massachusetts Division of Unemployment Security was presented and accepted.

ALBERT A. HONOR, *Secretary*

APPENDIX NO. 4

SOME COMMENTS ON THE PROCEEDINGS OF THE MEETING OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION

The House of Delegates of the American Medical Association convened in the Red Lacquer Room of the Palmer House, Chicago, on June 12, 1944. The speaker of the House, Dr. H. H. Shoulders, called the meeting to order at 10.15 a.m.

The preliminary report of the Reference Committee on Credentials through its chairman, Deering G. Smith, of New Hampshire, indicated an early registration of 150 delegates. Later in the week a registration of 170 delegates was reported out of a possible 175. This wonderful registration was one of the highest recorded at a meeting of the American Medical Association. It included delegates from the several states, one delegate each from Hawaii, the Isthmian Canal Zone and Puerto Rico, one delegate from the United States Army, one from the Navy, one from the Public Health Service, and one delegate each from the several sections.

This remarkable assembly indicated a strong interest of the members in the work of the House and also indicated the deep responsibility of each member. It also showed an appreciation of the seriousness of the problems that concern organized medicine in the United States.

Members of the reference committees showed a fair distribution among the several states, the specialties and the special delegates. Two members of the Massachusetts Delegation were each given a place on a reference committee. Dr. Charles E. Mongan was appointed a member of the Reference Committee of Amendments to the Constitution and By-Laws, and Dr. Walter G. Phippen was appointed a member of the Committee on the Report of Officers. Together with the secretaries from other states, Dr. Michael A.

Tighe, secretary of the Massachusetts Medical Society, was granted the privilege of attending the meetings of the House of Delegates in executive session.

It would be impossible to give a detailed report of the proceedings of the House of Delegates at this meeting. Suffice it to say that the report of the proceedings of the House of Delegates would cover ninety-four pages of the *Journal of the American Medical Association*. Your reporter will endeavor to select a few of the most important items discussed and acted upon at this meeting:

On December 31, 1943, the official membership of the American Medical Association carried the names of the 123,586 members. There was a net gain of 1876 above the number of enrolled members of December 31, 1942.

The Treasurer's Report no doubt will interest some of our members. The total wealth of the Association is \$5,711,833.17. The total income in 1943 was \$1,186,544.26. The income in excess of the expenses was \$718,873.76.

The report of the Council on Medical Service and Public Relations shows that this body is one of the most important councils of the American Medical Association. It is a little over one year old, and it made its first report at the meeting in June. The main office of the council is in the Association building in Chicago. There was also established a Washington office of the Council on April 3, 1944. It is located at 1835 High Street, N.W. Dr. Joseph S. Lawrence, executive officer of the Medical Society of the State of New York, was secured as a consultant, and the development of the office was placed under his direction.

The Council on Medical Service and Public Relations will probably become one of the most important Councils in the American Medical Association. Already it is advocating the creation of a federal department of public health, which will have a place in the President's Cabinet and will have under its control all medical activities of the federal government. As long ago as June, 1892, a communication from Dr. Henry O. Marcy, of Cambridge, Massachusetts, was received by the Massachusetts Medical Society asking for its influence in the creation of a Cabinet office for public health in Washington. The American Medical Association today advocates the same procedure.

The Council on Medical Service and Public Relations has taken up the matter of jurisdiction of the Children's Bureau of the Department of Labor in regard to furnishing medical aid to the citizens of the United States.

Let me read a paragraph from the proceedings of the House of Delegates.

A very clear statement was made by a number of physicians representing the American Academy of Pediatrics and the American Medical Association, and by some medical members of the Advisory Committee, to the effect that physicians, while concurring in the purpose of the program to render service to and free from anxiety the families of servicemen, wished it understood that they are aware of the potentialities of this program as a possible trial balloon, bridgehead or entering wedge looking toward the extension of medical service in point of time beyond the duration of the war and in breadth of scope, both as to kinds of service and as to groups served. They served notice on the Children's Bureau that they would wholeheartedly co-operate with the program for servicemen's families for the duration but not beyond. In response, officials of the Children's Bureau stated that the program was carried on under the authority of the Social Security Act, but under temporary appropriations visualized as national defense appropriations and therefore terminating six months after the peace. As to what they might advocate after the peace, officials of the Children's Bureau refused to be committed. Miss Lenroot stated specifically that after the peace there would be opportunity for any group to advocate any kind of program, conservative or liberal, which it might choose. Dr. Eliot stated that the EMIC program as it stands was an outgrowth of the emergency and was undertaken in response to a request from an Army general at Fort Lewis, Washington. She added that it was not a part of any "master plan" of which she had knowledge.

Following this meeting the Children's Bureau issued a revised set of regulations, which were published in the *Journal of the American Medical Association* on January 22, 1944.

Contained in Title V of the Social Security Act is authorization for experiments and demonstrations in medical

care. It was this authorization which permitted the Children's Bureau to start the Washington State Health Department on an experimental program in emergency medical and infant care for servicemen's wives and children in the vicinity of Fort Lewis. This is cited by the Children's Bureau as its legislative authority for starting new programs. Existing funds can be and are being used, but when the program grows very large, as in the EMIC situation, additional appropriations are necessary. A program for the care of rheumatic children now being developed is based on this same authority in Title V of the Social Security Act. This was extensively discussed at a meeting on October 6 and 7 by a group including representatives of many public-health agencies and also including the Advisory Committee to the Children's Bureau. In approximately twelve states demonstrations in the care of rheumatic fever patients are being carried out through maternal and child health divisions of the state health departments. Presumably this program may be extended by adopting it in other states. At present it is limited to the care of those who are not able to procure treatment privately. It would appear that the Children's Bureau considers medical treatment to be an integral part of public-health service in many circumstances. Extension of the rheumatic fever program to other states and to broader population groups is a logical step in the extension of federalized medicine by those who believe that such procedures are in the public interest.

The resolution offered by the delegates from California, asking that a change be made in the office of secretary of the American Medical Association and also in the office of editor of the *Journal of the American Medical Association* was refused by a vote of 144 to 9, which was a very flattering endorsement of the work of Dr. West and Dr. Fishbein.

Your reporter would like to call special attention to the speeches of Dr. Shoulders, speaker of the House of Delegates, Dr. James E. Paullin, former president, President Herman L. Kreisler and Dr. Frank H. Lahey.

I recommend that you studiously read the reports of the House of Delegates as reported in the June 24 and July 1 numbers of the *Journal of the American Medical Association*.

The Massachusetts Medical Society has contributed greatly to the promotion of sound underlying principles which act as guides to its members in the practice of medicine. The Society has given to the public sound advice as to public health and prevention of disease. It has furnished from its society members four presidents of the American Medical Association, namely, Dr. Henry I. Bowditch, Dr. Henry O. Marty, Dr. Herbert L. Burrell and Dr. Frank H. Lahey. Another member of the Society has been called to the presidency of the American Medical Association. He is especially equipped for the office and well informed as to the nature of the problems confronting organized medicine. He was a member of the House of Delegates for ten years. He was a member of the Board of Trustees for five years, having been its chairman. He is a practitioner of medicine and was formerly president of the American College of Physicians. Outside the field of medicine he has been for many years one of the administrators of one of the largest universities in the United States. He brings to the office outstanding ability in the way of large vision, capacity and rare executive ability. With such a record, I think you will agree with me when I say that Dr. Roger I. Lee is eminently qualified to be the president of the American Medical Association.

CHARLES E. MONGAN, *Senior Delegate*

APPENDIX NO. 5

REPORT OF THE SUBCOMMITTEE ON POSTPAYMENT MEDICAL CARE (BANK PLAN)

I am presenting this report to the Council without a meeting of the full committee having been held. For this I deeply apologize. My understanding was that nothing was to be said or made public about the plan until it was released by the American Bankers Association, with the consent of your committee. This was not to be completed in all details until some time about the middle of this month. Two days ago, however, I received a note with an enclosure from our good president requesting me to incorporate certain lines from the enclosure in my report to the Council. I, therefore, offer this report at this time not only with my apologies to the

entire committee but with my assurance to them that, as soon as the releases come through from the A.B.A., a meeting of the full committee will be held wherein they will be given an opportunity to offer suggestions or criticisms so that we may at the February meeting of the Council present our final suggestions and opinions on this subject.

As you all know, the spade work was done by the original committee under the able chairmanship of Elmer Bagnall, our president.

This plan was first devised by the Massachusetts Bankers Association, through its Consumer Credit Commission. It has been approved by the Council and is available to all banks in Massachusetts. It is proposed as a supplement to the Blue Cross and the Blue Shield.

The small-loan divisions of all banks in this state, as well as the small-loan companies, find that the second and third most frequent reasons given by people when applying for loans is for the payment of medical services. Obviously a real need exists for this plan. Let it be understood that the rates charged for this plan are low and easily explained. The charges are either added to or included in the doctor's fee. The patient signs a note for the agreed amount payable in six, eight, ten or twelve installments. A simple credit application is obtained, which the doctor or his secretary telephones to the bank. The facts are checked by the bank and the doctor is notified when the note is approved. In due course the signed note is presented by the doctor to the bank for discount. To secure the doctor and the bank against loss a reserve is set up out of each account on the books of the bank in the doctor's name. The need for the reserve depends on the credit of the patient and on the doctor's practice. By agreement, the reserve may be increased to cover even marginal situations, although the usual reserve will be about 10 per cent. It is paid to the doctor customarily as payment of each account is completed. As a result of the reserve feature the advance by the bank is lessened and the term of its payment is shortened so that the yield on the suggested rates compares closely with that of personal loans.

Whereas we are told by the banking interests that well over 90 per cent of all small loans issued by them are paid and whereas this gives us the assurance of collection by the bank's business methods, it must be understood that this plan is in no way the procedure of a collection agency. It is simply a method of making it easier for a man who eventually pays his bills to satisfy the legitimate claims of the physician and to relieve him and the doctor of repeated monthly statements. It will take time for the plan to become the customary procedure. Over the years its use will expand.

There are several brochures and pamphlets which are being passed around among you today which are connected with this plan. Your committee, when it first considered the expense of putting this plan over, felt that it might well have to be abandoned because of this factor. The minimum cost, it seemed to us, would be about \$600. None of us had the courage to come before this body and ask for that amount of money. When Mr. McCarthy, of the National Shawmut Bank, presented his plan to the American Banker's Association, however, they agreed to underwrite the expense of all the brochures, literature and publicity and to collect a proportionate amount of this expense from the member banks in this state. Massachusetts is the guinea pig. If the plan works out well here it will be extended to all the states in the union. Again, members of the Council, Massachusetts, there she stands!

I am going to close this report here, because I think that any details that may have been omitted can be better brought out in answering questions. And in doing this I shall not hesitate to call on Dr. Bagnall for assistance.

DANIEL J. ELLISON, *Chairman*

APPENDIX NO 6

REPORT OF COMMITTEE CONCERNED WITH PREPAYMENT MEDICAL CARE COSTS INSURANCE

An interim report on the progress of Massachusetts Medical Service is presented for your consideration.

SUBSCRIBER ENROLLMENT

It is approximately two years since you took the final steps that launched the corporation for prepaid medical care.

The growth since that time has been steady and progressive so that we are on a par with or ahead of the older plans in the country, excepting those of California and Michigan.

TABLE 1. *Blue Shield Enrollment.*

MONTH	NO OF CONTRACTS	NO OF PARTICIPANTS
1943		
January	123	230
February	216	428
March	257	503
April	193	396
May	101	217
June	386	868
	1,276	2,642
July	666	1515
August	579	1102
September	901	2262
October	1928	4435
November	2616	5726
December	2320	5486
	9,010	20,526
1944		
January	798	1795
February	597	1196
March	1599	3703
April	973	2356
May	838	1839
June	1293	2996
	6,098	13,885
July	1354	2782
August	1852	4006
September	2258	4808
	5,464	11,596
Gross enrollment (Sep- tember 30, 1944)	21,848	48,649
Cancellations	3,037	7,305
Net enrollment (Sep- tember 30, 1944)	18,811	41,304

Table 1 presents interesting data on growth. I shall simply note the high spots. As of January 1, 1943, we had enrolled 230 subscribers; in June, 1943, there were 2642 subscribers; at the turn of the year, in early 1944, there were 23,168 subscribers; in June, 1944, there were 37,053 subscribers; and as of September, 48,649 subscribers had been enrolled. The term subscriber means total participants in family groups. Actually, 21,848 contracts have been sold, so there is an average of 2.2 persons per contract in force.

Of considerable interest is the fact that during this period there were cancellations of 3037 contracts covering 7345 participants. This leaves a net enrollment in September of 41,304 participants on 18,811 contracts in force. These are distributed among 572 groups. These facts have just come to our attention and should be looked at critically and carefully. It must be done, however, with astuteness and without allowing precipitate action, because cancellations are a characteristic of the early history of all plans. Michigan had a complete cancellation by its original big sponsor, the Ford Motor Company, yet it went on and has enrolled 600,000 subscribers in the last four years. They were not panicked away from their basic concepts, which they had learned were correct because of such cancellations.

FINANCES

On the financial side we have been most fortunate. Table 2 portrays what has happened during this period. The figures are arranged in vertical columns that give the percentage distribution of funds for various items. Of great importance are the extreme variations in the percentages of the premium payments distributed to physicians. They vary from a low figure of 17.1 per cent to a high figure of 84.2 per cent. The corresponding figures for funds allotted to unrestricted surplus vary in a parallel fashion, the highest being a generous deposit on 68.2 per cent, and the lowest a deficit of 22.7 per cent, which occurred during the early days of the corporation. This means but one thing. Our experience today is so far from being stabilized that any significant departure from our present basis for disbursing funds would probably constitute poor business judgment. New factors coming into the picture may account for this fluctuation: tonsillectomy is the largest single item in all medical plans and comes in irregularly by seasons, with a year's waiting period; obstetric services are probably just now coming in significantly since there is also

a waiting period of one year for this type of medical service and, finally, six months ago all restrictions regarding pre-existing conditions were removed.

Our administrative costs, based on a contractual relation with the Blue Cross, have shown a steady decline until now they have reached the low figure of 13 per cent. You will recall that I have said at other times that it has been e-

TABLE 2. *Distribution of Blue Shield Funds.*

DATE	PAID TO PHYSICIANS	OPERATING COSTS	CREDITED TO LEGAL RESERVE	UNRE- STRICTED SURPLUS	CASH HANDLED
	%	%	%	%	
To August, 1943	34.0	94.7		-28.7	-\$2,844
September	25.3	37.3		37.4	
October	17.1	15.7		67.2	
November	18.2	13.6		68.2	
December	27.4	26.5		21.1	
To January, 1944	32.3	39.0		3.7	\$10,387
January	24.7	16.1		34.2	
February	46.2	16.4	25.0	12.4	
March	37.2	13.2	25.0	24.6	
April	46.2	14.3	25.0	14.5	
May	64.9	13.2	25.0	-3.1	
June	29.2	13.4	25.0	32.4	
To June, 1944	41.7	13.9	25.0	19.4	\$45,369
July	84.2	13.5	25.0	-22.7	

estimated that to administer a medical-service plan with joint contracts with the Blue Cross would require about 25 per cent of the premiums. Our expense for administration will show an increase in the immediate future. At the request of the Blue Cross, one of their employees, Mr. E. J. Cunningham, has been assigned full time to Blue Shield, and his services will be charged completely against us. In the future the services of a physician to help in reviewing claims will have to be engaged; for the past two years I have worked with the claim department, of course without charge, so that we might get on our feet financially.

We have done satisfactorily to the extent of having an unrestricted surplus of \$46,571.62. These funds must be conserved so that eventually we can include hospital medical care. It is the ruling of the Commissioner of Insurance, at least to date, that we cannot reimburse the society its \$25,000 until we have accumulated a surplus of \$255,000 surplus. At that time the requirement that 25 per cent of premium must be placed in a legal reserve that cannot be touched will also be removed.

CURRENT PROBLEMS

There are, of course, and probably always will be, the so-called "current problems." These problems, however, have been at an absolute minimum in Massachusetts as compared with the experiences encountered in other parts of the country. One hears an occasional disparaging remark, but the total overall interrelation between the profession, the subscribers and the Blue Cross has been healthier here than in any other place in the country, with due consideration of our size. So if minor problems present themselves, we should be shortsighted to precipitate ourselves into unwise action and departures.

Subscriber satisfaction has been hard to measure. It will never be 100 per cent. Our cancellations bear that out. The provision for nonpayment to nonparticipating physicians has been the chief cause of complaint. A few groups have said that the total cost for hospital and surgical contracts when combined is rather high. Nonpayment for nonhospitalized surgical conditions has been sometimes objected to. Absence of good faith on the part of participating physicians who agreed in a signed contract not to make additional charges to the under-income group but who have done so, even to the extent of charging as much again as the corporate plan allowed, has rightly caused mistrust of our purpose on the part both of the subscriber and of the industry in which he works. Nonparticipation or open criticism by industrial physicians has kept groups from joining.

Dissatisfactions among the profession have arisen at times but for the most part have been satisfactorily handled.

The fee schedule has been the source of some misunderstandings. By and large it has been considered to be equitable and fair. Certain individual items have not been fairly estimated. At my suggestion, and with the approval and instruction of the Board of Directors, all sections of the schedule will be restudied by committees appointed in the different specialties, and an effort to arrive at a fully acceptable revised schedule will be made. There of course cannot and will not be any general upward revision of the schedule. We may as well quit tomorrow as ask the subscribers to pay larger premiums, not for an increase in benefits, but for a larger stipend to physicians. This work, if accurately done, will take some time. Suggested changes must be weighed against our actual experience before being put into practice, to allow us to continue to operate in the black. Operating in the red, with consequent reduction in professional fees, has been the chief source of turmoil in other state societies; this we have been spared, only because we have operated in the black.

There are, of course, administrative problems. In the past there have been delays in paying doctors, but an attempt to correct this has been made by authorizing immediate payment of claims once they are cleared, rather than paying once a month. The service report has been revised so as to require less work. There is often a delay, up to six weeks or more, before the physician knows he has a Blue Shield case on his hands. This is sometimes due to delay on the part of the hospital in reporting a Blue Cross subscriber, whereby the corporation can tell from its files that the patient is also a Blue Shield subscriber, and so notify the physician. Much of this difficulty could be immediately eliminated if the hospitals would comply with a simple request I presented many months ago for their approval; namely, that the Blue Cross admitting form have a simple Blue Shield stub attached, on which the hospital admitting officer can write the patient's name, if a Blue Shield subscriber, and the doctor's name, tear the stub off and present it to the doctor. But all good things come slowly. Even that would not correct one situation in which a participating physician has in his drawer eleven incomplete forms, which he refuses to send in even after several letters from Boston.

PARTICIPATING PHYSICIANS

The final key to our success is the participation in this program by the bulk of the profession. If they come in, we must succeed; if they do not, we must inevitably fail with all the consequences entailed. Up to April, 1943, there were 3283 participating physicians; in the next year and three months, 294 more physicians had enrolled; and in the last three months (July, August and September), 86 more physicians have enrolled, giving a total of 3663 physicians. Withdrawals have been negligible. If the generous allowance of 5000 physicians in actual practice is taken, then 75 per cent of them are participating.

Why we need full support is clearly demonstrated by one experience. One large firm with over 2000 potential subscribers was considering the Blue Shield; they operate in the metropolitan area of Boston. They appointed a group of company officers to investigate participation. Their conclusion was that until free access to all hospitals and specialties was assured in the Boston area by a broader participation of physicians than now exists they would not join the Blue Shield.

Why is it that men refuse to support the effort of their own society in a co-operative endeavor with public bodies? Do they not see the dangers ahead?

Yes, it is true that, as they say, wages are high. But so is the cost of living, and those families under the established income limits are having a harder time and need the service more than ever before.

Yes, it is a fact that we are now prosperous. But every one talks in terms of retrenchment in the coming years. Then both the people and the profession will be fortified against adversity if this program is as widely used as the Blue Cross.

Yes, it is true that a man likes to feel that he can charge what his services are worth, even to the low-income group. But if a man's colleagues who are equally equipped as himself consider this program fair, why is it that he should expect a larger fee, particularly when it jeopardizes a patient's financial integrity or forces the patient from a self-support-

ing to a charity service. What solid ground has he to stand on if he quotes Chicago spokesmen to the effect that physicians deal fairly with patients by scaling fees downward according to their means, when his local colleagues say that he is a major cause of some of our troubles by scaling his charges inconsiderately upward, regardless of the burden on the stricken patient, so as to maintain a personally established and personally supervised scale of values.

Yes, it is a fact that no law has yet been passed that places medicine under governmental supervision. But the present administration will certainly continue its efforts for such medical legislation; furthermore, the opposing candidate has called for extension of social-security protection in medical care. And do not forget that the mechanism must be insurance on the same basis as that for unemployment—compulsion. Mayor LaGuardia has initiated a program with the full support of the industrial giants in his territory covering income groups up to \$5000. The conservative party of England has presented its own social-security program, which in essence is identical with that of Beveridge; Canada has nearly completed its program for socialized medicine. The United States Chamber of Commerce has recently voted approval of governmental provision of medical care for workers, in the event that industry fails to do so on a voluntary insurance basis. *Our only weapon against this current is the plea, Let's do it on a voluntary basis!* Yet some physicians refuse to co-operate. If a sufficient number continue to hold out we shall fail. Who, then, do these physicians think are going to fight for their rights—the large number of men who have made these efforts to date? No indeed! As a body, I think that they may decide that further effort is futile. It behooves the Massachusetts Medical Society to work ardently to see that its full membership participates in this program.

* * *

Finally, there is one matter on which I ask action. In probably an unorthodox fashion, the Committee Concerned with Prepayment Medical-Care Costs Insurance was continued after its work had been completed. With the incorporation of Massachusetts Medical Service, it really had no further standing. I used it as a means whereby I, its president, could bring you periodic reports of progress. That has worked well, and I believe that, in the future, the President, if a physician, should be allowed the privilege of your rostrum. At this point I should point out that the by-laws adopted by you do not provide that the president shall be a physician. We who studied the problem thought that he should be and probably would be a physician. We left it unspecified, however, so that if, in the distant future, there were solid reasons for having a layman as president, that could be done. At any rate the control of the by-laws with reference to such matters rests wholly in the hands of the voting members—the Executive Committee of the Society.

Let us clarify the picture by discharging a committee that has completed its work. Provided that a physician will be president during the evolution of the program, I assume that some proper way under the rules of procedure will be found to permit him to make periodic reports to the Council in behalf of the entire profession.

JAMES C. McCANN, *Chairman*

APPENDIX NO. 7

REPORT OF THE COMMITTEE ON EXPERT TESTIMONY

A special committee to consider medical expert testimony as given in courts was appointed by the president of the Massachusetts Medical Society in 1936. The original committee consisted of Drs. David Cheever, Francis P. McCarthy, Walter Phippen, J. J. Goodwin and George L. Schadt, chairman. The present committee consists of Drs. David Cheever, William Brickley, Francis P. McCarthy, Carl Bearse and Frank R. Ober, chairman.

The present committee held its first meeting two years ago and has met several times since to discuss the problem of medical expert testimony. It has become apparent to us that the duty of a special committee appointed to consider

medical testimony in courts is to report its findings and make recommendations to the Council of the Massachusetts Medical Society. Your committee has studied a mass of material which has been recently published covering many fields of legal medicine. It has studied recent articles published in medical journals on this subject, and there has been correspondence with some of the state medical societies which have organized plans adopted to their situations.

California and Minnesota have established permanent committees on medical expert testimony, and the Minnesota committee collaborates with a similar one from the state bar association.

It must be stated, however, that the Massachusetts Medical Society has not been remiss in this matter since two of our standing committees — the Committee on Medical Defense and the Committee on Ethics and Discipline — have settled many such problems for several years. These two committees have their special functions, which entail a good deal of work, so it does not seem wise to overload these two bodies with a job which may not necessarily come into their province.

Medical expert testimony is in a constant and changing fluid state. In every case in which a physician is involved, there may be a problem to be solved by the medical profession. We as a group are concerned with ordinary as well as expert testimony. Testimony may be given in hearings, before industrial accident boards, before judges and before juries, when grievances occur or when there are trumped-up cases. There should be some new permanent machinery set

up by the Society in order that the testimony of poor or bad witnesses may be reviewed and suitable methods advised for correction or for disciplining the offending medical witness, or lawyer, or both.

This committee should be a standing one. The Massachusetts Bar Association might be invited to set up a similar committee among its members, and these committees should be given authority to collaborate. It is important that the committee be a standing one. It should also collaborate with the Committee on Ethics and Discipline and the Committee on Medical Defense. All cases with evidence of bad testimony should be heard and investigated by such a committee, which should be empowered to make recommendations to the Committee on Ethics and Discipline.

The functions of a standing committee on medical expert testimony should be twofold: first, punitive and, second, educational. It should set up a program of education for the physicians. It should collaborate with all the parties concerned, and above all it should not endeavor to solve all the many controversial problems at once.

This special committee therefore recommends:

(1) That a standing committee of five or more, to be called the Committee on Medicolegal Problems, be appointed by the President.

(2) That the by-laws of the Massachusetts Medical Society be amended to provide for such a body.

CASE 30511

PRESENTATION OF CASE

A seventy-six-year-old woman was admitted to the hospital because of abdominal pain.

Five days prior to admission, while sitting quietly in the evening, the patient felt a rather severe colicky pain below the left breast just outside the midline. This disappeared during the course of the night, and for the next two days she felt well and was fairly active. Two days before entry the pain recurred in the epigastrium and was intermittent in character. A physician prescribed some pills; these made her feel nauseated, but she did not vomit. On the same day she had a bowel movement; this was followed by constipation, which failed to yield to a saline cathartic. On the day before admission the pain shifted to the right lower quadrant. It was constantly present and was aggravated by movement in bed. The temperature rose to 101°F. There was no vomiting or cough.

For six and a half years prior to entry the patient had been known to have hypertension, with pres-

ures of 160 to 170 systolic, 100 to 110 diastolic. Six months before admission the blood pressure was 190 systolic, 100 diastolic.

Physical examination revealed an acutely ill woman. There was exquisite tenderness over the right half of the abdomen, which was thought to be most marked in the right upper quadrant over the gall bladder. Practically no muscle spasm was present. Palpation in the right lower quadrant produced pain referred to the left lower quadrant. Tenderness in the right costovertebral angle was demonstrable when she lay on her back, but this disappeared when she turned on her right side. The psoas sign was negative. There was no rectal tenderness.

The temperature was 101°F., the pulse 88, and the respirations 24. The blood pressure was 190 systolic, 90 diastolic.

Examination of the blood revealed a white-cell count of 18,000, with 80 per cent neutrophils. The hemoglobin was 15.8 gm. per 100 cc. The urine had a specific gravity of 1.032, with a ++ test for albumin and a sediment containing 15 white cells, 25 epithelial cells and an occasional granular cast per high-power field. The serum nonprotein nitrogen was 47 mg. per 100 cc., and the blood sugar was normal.

Two hours after admission a cholecystectomy was performed under ether anesthesia. A tense, distended, edematous gall bladder surrounded by recent inflammatory adhesions was found. It had a queer yellowish color, with greenish areas, and appeared unlike any acute gall bladder that the surgeon had seen in the past. The common duct was apparently of normal size. The head of the pancreas was normal to touch but not entirely normal in appearance; there was no fat necrosis.

*On leave of absence.

The pathological report was acute and chronic cholecystitis.

Following operation the patient was quite drowsy, although she received little medication. She continued to complain of pain on the slightest movement. An electrocardiogram revealed auricular premature beats but no evidence of heart disease.

On the afternoon of the third postoperative day the patient suddenly became dyspneic and cyanotic, although the lungs remained clear. The blood pressure fell, and she became stuporous, failed to recognize her family and expired about three hours after the onset of the acute episode.

DIFFERENTIAL DIAGNOSIS

DR. REGINALD H. SMITHWICK: We have a woman in the older age group who was operated on approximately one week after the onset of symptoms, an acute near-gangrenous gall bladder being removed. She died suddenly a few days following operation and three hours after the onset of an acute episode consisting of dyspnea, cyanosis and low blood pressure. The questions seem to be, What was the cause of death, and did the acute gall bladder represent the full extent of the pathology?

Certain symptoms, signs and laboratory data are given. The first symptom was pain, apparently quite severe and sudden in origin, located in the left anterior chest at about the level of the sixth or seventh dorsal vertebra and to the left of the midline; it lasted several hours and never recurred. Such a pain might have arisen from pathology in a thoracic organ, such as the heart, the lung or the aorta, but no evidence of cardiac or pulmonary disease was noted. It could have been referred pain from an upper abdominal viscus, such as the pancreas or gall bladder, but that, although wholly possible, is unusual. After two days without symptoms the onset of epigastric pain, intermittent in character, was noted. This was associated with nausea and constipation, and after twenty-four hours shifted to the right lower quadrant. Following this it was continuous, aggravated by motion and associated with fever, an elevated white-cell count and marked tenderness over the right abdomen, maximal over the gall-bladder region, with practically no spasm. All this seems consistent with the finding at operation of an acutely inflamed, distended gall bladder. It is rather surprising, however, that no mass was felt in view of the absence of spasm, and the pain on motion is a little more marked than one would expect since pain at this stage of acute infection of the gall bladder is usually associated with spasm and a mass due to the implication of the omentum and colon by local peritonitis. One gathers the impression that the surrounding peritonitis was not marked, since the gall bladder was removed, the common duct said to be normal in size, and the head of the pancreas normal to palpation but not in appearance. The latter

suggests the possibility that some form of pancreatitis also existed. An extension of this process subsequent to operation might explain the persistence of pain on motion following operation, — I assume that pain from the incision was discounted, — the drowsiness of the patient, owing to toxemia, and the sudden death with dyspnea and cyanosis and circulatory collapse without evidence of pulmonary or cardiac disease.

One might speculate regarding other possibilities. In a woman of this age, with systolic hypertension, indicating disease of the large blood vessels, vascular accidents may be expected. I am inclined to discount the moderately elevated nonprotein nitrogen as being the result of dehydration and hemoconcentration and to exclude uremia as a cause of death. There seems to be no good evidence of a cerebral accident or coronary thrombosis. Other vascular accidents, such as thrombosis of the mesenteric vessels and rupture of a blood vessel, also seem unlikely, although the possibility of dissecting aneurysm should be mentioned, largely because of the sequence of symptoms: first, thoracic pain, then, upper abdominal pain and, finally, lower abdominal pain. The unusual appearance of the gall bladder, which was tense, distended, edematous and yellowish rather than the more usual reddish purple, with greenish areas, was probably the result of the proper combination of obstruction, infection and the transudation of bile pigments into the wall. I have seen a few somewhat similar acute gall bladders. In a patient of this age group, pulmonary embolism is a possible cause of death, but it seems as if some physical signs, such as distended neck veins and pulmonary edema, pointing to this should have developed in three hours. This is also likelier to cause death after a longer interval following operation. Rupture of a dissecting aneurysm into the pleural or pericardial cavity usually results in death in a few minutes rather than in hours. Hepatic insufficiency seems unlikely in the absence of jaundice. Adrenal insufficiency due to hemorrhage into the medullas of the adrenal glands is a rare cause of death with circulatory collapse.

A rapidly progressing pancreatitis following the acute cholecystitis seems a possible explanation for the persistence of abdominal pain and the continued downward progress of this patient after operation, with sudden death forty-eight hours later.

DR. HELEN PITTMAN: This woman had had hypertension for six and a half years. She was an extremely active woman for her age. When I first saw her she was unusually well. I could never make any diagnosis except for a certain amount of arteriosclerosis and hypertension. In the last year she had been aging rapidly. I saw her about three months before admission, and at that time she had lost her vitality, tired easily and had more hypertension, but nothing new. I did not hear from her again until seven o'clock in the evening of admission. I was

struck by the fact that she had severe pain. She was a person who had always been well and who had never been a complainer, and she was obviously in extraordinarily severe pain on the slightest motion. There was exquisite abdominal tenderness without spasm or with so little spasm that it was disproportionate to the amount of tenderness. I called for Dr. McKittrick, and the rest of the story is his.

DR. LELAND S. MCKITTRICK: Dr. Smithwick gave an excellent discussion, and I was pulling hard hoping that he was going to take a long shot and make the correct diagnosis. He made the logical one, however.

I did not know what this patient had. I would not have operated if I could have been sure that she did not have an early rupture of the gall bladder. It seemed that tenderness was definitely present in the gall-bladder region, and whereas we suspected acute cholecystitis, I was not sure enough of the diagnosis to refuse operation.

It was a queer looking gall bladder and was as described in the abstract. I did not attempt to describe the appearance of the pancreas because I could not. It just did not look normal even though it felt all right. There was no fat necrosis. I was fairly sure that the patient did not have an acute hemorrhagic pancreatitis. We took the gall bladder out and did not think too much about it until I opened it and did not find any stones. I commented to the small but select group assembled at one o'clock in the morning that I had not seen more than one or two acute gall bladders that did not contain a stone. I was worried about it. I did not notice anything abnormal in the liver.

We finished the operation but were unhappy in our minds, thinking probably that this was one of those conditions for which we do not know the explanation and that it was an acute cholecystitis. I did not know what happened postoperatively except that she died, and I was totally ignorant about what was going to be found until I saw the autopsy.

CLINICAL DIAGNOSIS

(Acute cholecystitis.)

DR. SMITHWICK'S DIAGNOSES

(Acute cholecystitis.)

Acute pancreatitis.

ANATOMICAL DIAGNOSES

Thrombosis of celiac axis and hepatic, cystic, superior mesenteric and splenic arteries.
 Infarction of liver, spleen and intestine.
 Arteriosclerosis, severe, generalized.
 Cardiac hypertrophy, hypertensive type.
 Pulmonary emboli, multiple, small, recent.
 Operation: removal of gangrenous gall bladder.

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: When the abdominal cavity was opened, the striking finding was early gangrene of the entire small intestine and part of the right colon. The infarction was caused by recent thrombosis of the superior mesenteric artery which must have developed postoperatively, since it was not seen at operation.

The cause of this patient's preoperative symptoms was unique in the experience of this laboratory — thrombosis of the celiac axis. The abdominal aorta showed severe arteriosclerosis, the intima being extensively frayed and fragmented. The orifice of the celiac axis was surrounded by a calcified plaque and the lumen was occluded by a gray adherent thrombus about 2 cm. long (Fig. 1). There was

FIGURE 1. Diagram of Abdominal Aorta and Its Branches. The shaded areas represent the older thromboses, whereas the black areas represent the more recent ones.

thrombosis of the hepatic artery and of its two branches well into the liver, with the result that the liver was extensively infarcted. What the surgeon removed was an early gangrenous gall bladder due to thrombosis of the cystic artery. The left gastric branch of the celiac axis was uninvolved. Two of the terminal branches of the splenic artery

ere thrombosed, probably by emboli from the iliac artery, with resultant infarcts of the spleen. The pancreas was not involved. Whether the cholecystectomy in some way started off this thrombosis I do not know, but I feel fairly sure that this occurred after the operation, because this thrombus was quite recent when compared with the thrombus in the celiac artery. Around the orifice of the superior mesenteric artery there was also an atherosclerotic plaque, which probably had something to do with the formation of this thrombus. There was no involvement of the renal or inferior mesenteric arteries.

Ordinarily one does not get such widespread infarction of the liver without damage not only to the hepatic artery but also to the portal vein. In this woman the portal vein was normal. These infarcts are similar to those produced experimentally by ligation of the hepatic artery, but there, of course, the occlusion is sudden. Here it probably was not so sudden. The presence of relatively old thrombi in the distal portions of the hepatic arteries and of a more recent thrombus in the proximal portion suggests that the hepatic occlusion began as emboli from the celiac artery. There were a few small emboli in the terminal vessels of the lungs.

DR. MAURICE FREMONT-SMITH: I wonder if the finding of extreme tenderness without spasm is helpful in making a diagnosis. I remember a patient at the Peter Bent Brigham Hospital, when I was a house officer there, who had extreme pain and tenderness but no spasm and who was found to have mesenteric thrombosis. Is the absence of spasm an important physical differentiation?

DR. McKITTRICK: I do not know.

DR. CASTLEMAN: I do not believe that this patient had mesenteric thrombosis when she came in. She had thrombosis of the celiac axis, and the pain was due to the gangrene of the gall bladder.

DR. FREMONT-SMITH: In other words, it was not inflammatory but circulatory. That is my point: there was not the amount of spasm that one would expect with an inflammatory process.

DR. SMITHWICK: Severe visceral pain may occur without spasm of the abdominal wall. If, for example, one blows up the small intestine with a balloon, thus creating intense, agonizing pain, the abdomen is flaccid.

DR. McKITTRICK: Spasm is an uncertain thing, particularly in old people. We see not a few patients with peritonitis who have no spasm. It is such a hard thing to evaluate that I cannot say how much she had, although she did have some.

DR. FRANCIS D. MOORE: One can have spasm over an infarcted loop of small bowel, once it has become gangrenous.

DR. McKITTRICK: But in such cases there is peritonitis. Whether spasm occurs before infection has set in, I do not know. It is a good point.

CASE 30512

PRESENTATION OF CASE

A seventy-year-old man was admitted to the hospital in coma.

The patient had apparently been well until the day before admission, when he developed pain in the left upper quadrant associated with nausea. Because of his condition no data concerning the character and radiation of the pain could be obtained, other than that it was apparently severe and constant. Several hours later, following an attempt at high colonic irrigation, the patient vomited black foul-smelling material. He was admitted to a community hospital and given morphine, following which he became stuporous and remained so. His skin was cold, and it was difficult to administer intravenous fluids. A white-cell count was said to have been 20,000. He was transferred to this hospital the following morning. For two or three weeks prior to admission he had been constipated.

The patient had had a cholecystectomy twenty-eight years previously, and an operation for a ruptured appendix two years later. Five years before entry he had had a prostatectomy, from which it took him nine months to recuperate. Both parents were said to have died of diabetes.

Physical examination revealed a well-developed and well-nourished comatose man. The pupils were contracted, and the tongue was dry. The skin of the extremities was moderately cold and clammy. There was tenderness in the left upper quadrant, where a firm, ill-defined, pulsating mass could be felt. Percussion over the area revealed dullness but no flatness. Peristaltic sounds were distinctly audible. Rectal examination revealed a depression in the region of the right lobe of the prostate, the remainder of the gland being firm but not enlarged.

The temperature was 101°F., the pulse 110, and the respirations 16. The blood pressure was 96 systolic, 80 diastolic.

A white-cell count was 13,400. The urine had a specific gravity of 1.020, with a +++ test for albumin, and the sediment contained many coarsely granular casts, 10 white cells and a rare red cell per high-power field; there was no sugar or diacetic acid. A blood sugar was 121 mg. per 100 cc. The serum nonprotein nitrogen was 43 mg., and the protein 7 gm. per 100 cc. The chloride was 98 milliequiv. per liter, and the carbon dioxide content 30.1 milliequiv.

A roentgenogram of the chest revealed only a high diaphragm bilaterally. X-ray examination of the abdomen showed gas in the stomach and colon,

but none in the small bowel. On the left side, near the transverse process of the third lumbar vertebra in the course of the ureter, there was a small ill-defined shadow of the density of calcium.

Catheterization on admission revealed only 5 cc. of urine in the bladder. A cystoscopy was performed, but no obstruction to the left ureter could be demonstrated, there being good urinary output from the kidney. Ten per cent dextrose in water, followed by 5 per cent dextrose saline solution, was administered intravenously. The pulse rate rose to 140, and the respirations to 30. The abdomen became tympanitic and diffusely tender, but peristalsis remained good. There was some flaccidity of the left leg, and the right corner of the mouth drooped, but no abnormal reflexes were obtained. The white-cell count rose to 17,700, and the non-protein nitrogen to 59 mg. per 100 cc. On the second hospital day the patient expired.

DIFFERENTIAL DIAGNOSIS

DR. FRANCIS D. MOORE: I should like to start off by looking at the x-ray films.

DR. GEORGE W. HOLMES: As already stated, the diaphragm is high on both sides, but the right half is definitely higher than the left. There is a great deal of gas in the stomach, but I do not believe that the colon is particularly dilated, although it is a little unusual that there should be so much gas there without any in the rectum. I suppose they thought that this area of calcification might have been a stone in the ureter. It does not look much like one. Since the ureter was catheterized, there is no reason to suspect that there was a stone.

DR. MOORE: Is the kidney abnormally displaced to the left?

DR. HOLMES: Yes; not only the kidney but also the ureter along its entire length.

DR. MOORE: Does this big area of "nothingness" suggest a mass that could be the one displacing the kidney?

DR. HOLMES: Yes; but I am not too certain about it.

DR. MOORE: We have here a seventy-year-old man who had pain in the left upper quadrant. I have gone over the record and tried to reconstruct the time relations. He was transferred to a local hospital, was given morphine and went into shock and coma all on the same day. The next day he came here, possibly with peritonitis, and the following day he died. Forty-eight hours transpired from the first acute symptom to death, with no operative procedure having been done. The pathologic process was a rapid one.

There are features in the record to suggest a great many diagnoses: gastric or colonic neoplasm, aortic aneurysm, ureteral stone, cardiac failure, chronic vascular nephritis, mesenteric thrombosis, cerebral thrombosis and benign hypertrophy of the prostate. I shall attempt to select the one

most responsible for his demise, although in all probability he had several diseases.

For three weeks prior to admission he had been constipated. Any man of seventy has a right to intermittent periods of constipation; however, since he was in coma and the history was obtained only from the family, they must have observed that he was having real trouble for three weeks. This suggests that the gastrointestinal tract was implicated. We find that after he received a colonic irrigation he vomited black foul-smelling material, which further suggests that he might well have had some sort of an obstructing lesion, even a gastrocolic fistula resulting from a neoplasm. But I am disturbed by the normal gas shadow in the stomach. The colon looks normal; there are no signs of tumor, and there is no abnormal distention. As a matter of fact I believe that is as good an air picture of that region as one could hope for. The patient had a tender mass in the left upper quadrant, which fits with the concept that he had a neoplasm in this region. He developed signs of peritonitis, compatible, of course, with a tumor that has ruptured or undergone necrosis. The white-cell count and temperature went up, which is also consistent with that general idea. There is no note of a guaiac test on a stool, which is unfortunate. One thing in the story is against gastrointestinal neoplasm; namely, at the time of admission to the hospital he was a well-developed and well-nourished man and one would not expect him to be such if he had a gastrointestinal neoplasm that had been there long enough to perforate, especially if a gastrocolic fistula had formed.

Renal tumor is possible, although the statement about the urine makes that unlikely; furthermore, the kidney was displaced in the wrong direction for a tumor of the parenchyma. The spleen or pancreas could have been involved, but it is hard to see how a tumor of the spleen or pancreas could produce death in forty-eight hours, even though it had undergone necrosis. Tumors of the pancreas associated with pancreatitis are, to my knowledge, rare.

How about aortic aneurysm? That seems like a good possibility. The mass pulsated. Incidentally, that does not make it an aneurysm because in an older person any mass that presses on large blood vessels pulsates. A big aneurysm at this point, big enough to be felt from the outside, would have to include a great many other vessels — the celiac axis, one or both mesenteric arteries and probably one or both of the renal arteries. So its formation would really be a disastrous event and could kill a person in a short time, as this lesion did. Against it, however, we have no previous history of heart disease or of hypertension, and the heart was not enlarged, according to the record. The facts that there was no calcification in the aorta and that the patient continued to have good urinary output are also against aneurysm.

The concept of ureteral stone is ruled out by the cystoscopic findings. I shall not spend further time on it.

How about the heart? It was not enlarged, but when he received 10 per cent dextrose in water and 5 per cent dextrose in saline solution, — it does not say how much or how fast, — the pulse went to 140 and the respirations to 30, which suggests that he did not have much cardiac reserve. Kidney damage is well substantiated by the record — albumin, casts, white cells, a rare red cell and a rising nonprotein nitrogen level; perhaps the last was due to dehydration, and yet in spite of the dehydration he could not concentrate over 1.020. So we are justified in saying that he had a chronic renal lesion. The fact that he had only 5 cc. of urine in the bladder was perhaps due to shock.

A cerebral vascular accident seems likely because he went into coma rapidly. One might ask, Could the coma have been due to the morphine? It is worth while pointing out that when he came to this hospital he was still in coma but the respirations were 16; hence, morphine poisoning seems unlikely. Since he had a flaccid left leg and something wrong with the mouth, he probably had had a cerebral vascular accident. Venous mesenteric thrombosis can be rapidly fatal and can at times produce a mass, but the mass is due to the matted loops of gangrenous bowel and I should not expect that it would transmit pulsation from the aorta.

Pulmonary embolism is also possible, but it may have been masked by other things.

I have mentioned all the pathologic processes that are suggested by the record. There are points pro and con on all of them, but I am going to take as my first diagnosis a malignant lesion of the gastrointestinal tract, either in the stomach or large bowel, I do not know which, with local rupture producing peritonitis and shock. I hypothecate that he was given morphine while in shock, that this further depressed his activity and possibly lowered his blood pressure and that he then developed a cerebral thrombosis, which produced neurologic signs. I believe that he also had arteriosclerotic heart disease, chronic vascular nephritis and probably benign hypertrophy of the prostate. As a second choice, I shall say aortic aneurysm.

I should like to ask Dr. Holmes, now that I have made my diagnosis, what his x-ray diagnosis would be purely on the basis of the displaced kidney.

DR. HOLMES: There is just a possibility that that was simply technical because of the way the film was taken. If the kidney is displaced one would have to think of a retroperitoneal mass. I should not expect a ruptured viscus to do that unless there was an abscess behind it.

DR. MOORE: Would you expect an aortic aneurysm to do it?

DR. HOLMES: That is a possibility, but I should think that an aneurysm capable of doing that would also have eroded the bodies of the vertebrae, provided that it had been there any length of time.

DR. MOORE: And also completely destroy the renal vessels, which it did not do.

DR. HOLMES: It might be a retroperitoneal mass of some sort, but I cannot go any farther.

DR. MAURICE FREMONT-SMITH: This was an extremely interesting case. Additional history was obtained afterward. For three months before entry this man had had pain in his back, for which he had gone to an osteopath several times for treatment, with apparent improvement. Both dorsalis pedis arteries were palpable and pulsating. Anuria was a striking part of the picture. Although Dr. Colby reported that the kidneys were excreting urine, we catheterized him twice without obtaining any. The mass was definitely pulsating. We wondered if it was a mass lying over the aorta, in spite of the fact that it was well out to the left.

DR. MOORE: Was it expansile?

DR. FREMONT-SMITH: I cannot say, but it had a definite pulsation. We thought that he had had a vascular accident, but the pulsating dorsalis pedis arteries argued against a dissecting aneurysm. Our tentative diagnosis was a rupture of an aneurysm of the renal artery, with a retroperitoneal mass of blood connected with a vessel. We also thought of the possibility of a cerebral accident, but did not believe that it could have been the cause of death.

DR. BENJAMIN CASTLEMAN: Dr. Moore, have you anything more to say?

DR. MOORE: These points certainly make me incline toward aneurysm more than anything else.

CLINICAL DIAGNOSES

Aneurysm of left renal artery, with rupture into retroperitoneal space?
Cerebral thrombosis.

DR. MOORE'S DIAGNOSES

Gastrointestinal neoplasm, with rupture and peritonitis?
Aortic aneurysm, with rupture?
Arteriosclerotic heart disease.
Chronic vascular nephritis.

ANATOMICAL DIAGNOSES

Aneurysm of abdominal aorta, with rupture into left retroperitoneal space.
Arteriosclerosis, generalized.
Cardiac hypertrophy, hypertensive type.

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: The autopsy showed a large retroperitoneal mass, which proved to be a hema-

toma, measuring 22 by 14 by 10 cm., that surrounded the left kidney, adrenal gland, renal artery and ureter and was surmounted by the spleen and pancreas. The hematoma had resulted from a rupture of an aortic aneurysm beginning below the level of the renal arteries and extending to the bifurcation.

DR. MOORE: Where was the kidney in relation to the mass?

DR. CASTLEMAN: Completely surrounded by the hematoma.

DR. MOORE: Was its circulation obliterated?

DR. CASTLEMAN: No; the aneurysm occurred below the level of the renal artery. The hematoma

surrounded the kidney and renal artery, but the artery was not intrinsically involved. The anuria was probably due to shock. There was slight vascular disease of the kidney.

DR. HOLMES: It is unfortunate that we did not have better films of the kidney. I suppose the patient's condition was too poor.

DR. MOORE: Was anything found in the brain?

DR. CASTLEMAN: It has not been sectioned yet. Small multiple thrombi will probably be found to account for the symptoms.

DR. HOLMES: Were the vertebrae involved?

DR. CASTLEMAN: No.

CHRISTMAS, 1944

CHRISTMAS this year, as never before, will be celebrated by Americans in many lands and in strange anners. In improvised hospitals from Alaska to India and from New Zealand to the fields of Flinders, American doctors and nurses will be bringing the traditional cheer of the season to many thousands of their sick and wounded countrymen. The hard-pressed islands of the Pacific will feel its temporary impact, and it will be briefly acknowledged in the stubbornly defended mountains of northern Italy and in the rutted mud of western Europe.

December 25, in short, is Christmas, and it will evoke the same images, nostalgically, and have the same meaning to millions of modern crusaders upon

whom the sun now never sets as it will in their homes in Massachusetts or in California or in Montana.

We have a right, we hope, to believe that this Christmas is witnessing the peak of our foreign military traffic; that before another season of giving has come around, we will have ceased to include among our overseas packages those of reeking tubes and iron shards; that our hard-pressed enemies will have decided to cry "Enough," and will embrace once more — or for the first time — the doctrines of peace on earth and of good will toward other men.

Our victory is in sight, but it is at the end of a long road that is still not too close to its ending. We can be thankful that we are approaching that end, however, in the company of a good fellowship, all bent on the same goal and with the same motives. It is as Paul, approaching Rome in some tribulation, found that the brethren had come to meet him, even as far as Appii Forum: "Whom, when Paul saw, he thanked God, and took courage."

Christmas provides as good a motive for referring to the Scriptures as any, if a motive need be sought, so let us add one more singularly appropriate quotation, from the best loved Psalm: "Thou preparest a table before me in the presence of mine enemies: . . . my cup runneth over."

PROPHYLACTIC USE OF SULFONAMIDES

THE herding and alteration in the mode of living of young adults in time of war inevitably result in epidemics of viral and bacterial disease, especially infections of the upper respiratory tract. The present war has been no exception, although there have been striking differences in its epidemic diseases from those of World War I. Fatalities and serious illnesses have been greatly diminished as the result of new therapeutic agents, but the loss of manpower days as the result of upper respiratory infection has been and continues to be a serious military problem.

Reports of Group A hemolytic streptococcus epidemics among military populations are now appearing in the medical literature. Not only have there been large numbers of cases, but also the frequency of associated rheumatic fever makes this problem one of great importance to the services,

especially in the training of military personnel. The latter causes long periods of illness, and those who are so afflicted must either be discharged from the services or run the danger of repetitive or recurrent disease.

It is natural that the armed services have developed prevention programs for the curtailment of hemolytic streptococcus infections and rheumatic fever. The reports to date largely concern the administration of small daily doses of sulfadiazine to large numbers of personnel. Holbrook,¹ Coburn² and Keith³ have recently reported such studies. These papers offer interesting material and data that require much thought and even philosophical speculation. All three authors agree that such sulfonamide prophylaxis sharply decreased the volume of streptococcal disease in the respective populations. In one instance it was indicated that the incidence of rheumatic fever was reduced, parallel to that of streptococcal diseases, and in another this mass prophylaxis was reported as effective in preventing the development of disabling sequelae caused by these bacteria.

A further report on sulfonamide prophylaxis in the armed forces appears elsewhere in this issue of the *Journal*. In keeping with the previous reports, Dr. Hodges reports a diminution of bacterial disease, especially streptococcal infections, as well as rheumatic fever, in the treated groups. Attention should be particularly directed to one of the figures of his report, which shows a continued rise in the streptococcal infections in the control group coincident with a sharp fall in these infections in the treated group. This appears to be the most convincing information yet published.

These reports are of broad significance and importance. The data as yet available, however, do not permit accurate appraisal of the results. Variations in susceptibility, length of military experience, the composition of individual units, the length of service in a given station, housing and so forth make such disease-control measures a complex problem, the evaluation of which is fraught with difficulty. There can be little doubt that more than suggestive evidence of the immediate success of sulfonamide prophylaxis is presented. Eventual analyses with more detailed information may indicate that factors other

than the drug prophylaxis were at least partially responsible for the results obtained.

A recent editorial in the *Journal* discussed the dangers of continuous sulfonamide therapy.⁴ The development of sensitization to the sulfonamides and the creation of drug-resistant strains of bacteria were stressed as possible deterrents in this type of prophylactic control. Several new developments suggest the pertinence of these previous remarks, and it seems advisable to re-emphasize some of the possible and inherent dangers of such mass prevention studies.

Little can be added concerning the development of sensitivity or toxic reactions to the drug. Reports continue to indicate that such cases are rare. The report of French and Weller,⁵ however, needs emphasis. Fatalities as the result of myocardial changes following therapeutic doses of sulfonamides are apparently increasing, and one can only wonder what will develop in young men who have received small prophylactic doses of sulfonamides when they are given large therapeutic doses at a later period. The future alone will give the complete picture.

The question of drug-resistant strains seems more immediately pertinent. Hendry⁶ has demonstrated the development of drug-resistance by a Group A hemolytic streptococcus. Since virulence or pathogenicity seems unrelated to drug-fastness, the possibility of the development of epidemics with drug-fast strains seems entirely tenable. Indeed, Wright, Cruickshank and Gunn⁷ have reported their inability to control the spread of a drug-resistant Group A (Type 6) hemolytic streptococcus in a measles ward by sulfonamide prophylaxis. The ease with which strains may become drug-resistant remains to be determined, as well as many other puzzling features. It seems not unlikely that the widespread therapeutic and prophylactic use of sulfonamides will eventually produce many resistant strains and that penicillin will prove to be as necessary in these as in gonococcal infections.

Another feature of such prevention programs remains unexplored. Little is known concerning what role long-continued sulfonamide prophylaxis plays in the development of antistreptococcus immunity. It is possible that protection at one time results in a continuation of susceptibility and the develop-

ment of appreciable patterns of illness on later exposure to infection. Some information concerning this may be available in the future.

Military necessity will, of course, dictate the continuation of sulfonamide prophylaxis. Even in such populations the alleviation of an immediate problem may ultimately prove to effect adversely the future health of service personnel. So far as civilian populations are concerned, there seems little justification for the wholesale and uncontrolled use of long-continued sulfonamides, save on a purely experimental basis, with a carefully thought-out and controlled study. Furthermore, attention should be directed to other measures for the control of streptococcal infections that are not accompanied by the dangers and difficulties mentioned above. Dust control (by the oiling of floors and bedclothes), sterilization of the air by ultraviolet irradiation and the use of aerosols, ventilation, improved methods of housing and so forth may be mentioned as procedures of probable benefit.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

BARONE — Anthony Barone, M.D., of Boston, died December 8. He was in his forty-ninth year.

Dr. Barone received his degree from Tufts College Medical School in 1917. He was also a dentist and registered pharmacist. He was a member of the American Medical Association and the Massachusetts Dental Society.

His widow, four daughters, five brothers and two sisters survive.

GODDARD — Frederick C. Goddard, M.D., of Uxbridge, died November 7. He was in his fifty-second year.

Dr. Goddard received his degree from Tufts College Medical School in 1917. He enlisted in the army immediately following his internship at St. Elizabeth's Hospital. For the past twelve years he has been a member of the visiting staff of Milford Hospital. He was a member of the American Medical Association and a past president of Thurber Medical Association.

His widow, two sons and a daughter survive.

KELEHER — William H. Keleher, M.D., of Woburn, died December 4. He was in his seventy-sixth year.

Dr. Keleher received his degree from Harvard Medical School in 1892. He was a director of Choate Memorial Hospital and a former medical examiner of the Fourth Middlesex District. He was a member of the American Medical Association, and was president of the Middlesex East District Medical Society in 1913.

His widow, four sons, a daughter and a sister survive.

LEHNHERR — Earl R. Lehnher, M.D., of Brookline, died December 4. He was in his forty-second year.

Dr. Lehnher received his degree from Harvard Medical School in 1931. He was a staff member at the New England Deaconess Hospital and the Palmer Memorial Hospital and was associated with the Allergy Clinic of the Massachusetts General Hospital. He was a member of the American Medical Association.

His widow and a son survive.

PERKINS — Roy S. Perkins, M.D., of Lowell, died December 3. He was in his fifty-fifth year.

Dr. Perkins received his degree from Bowdoin Medical School, Brunswick, Portland, in 1914. After practicing for two years in Lowell, he entered army service in 1917 and served overseas for 14 months as a captain in the Medical Corps. He conducted an x-ray laboratory in Boston and served as radiologist at St. John's and St. Joseph's hospitals in Lowell, at the Peabody and Salem hospitals and at the Massachusetts State Hospital in Tewksbury. He was president of the staff of St. John's Hospital and a past president of the staff of St. Joseph's. He was a fellow of the American X-ray Society and a member of the American Medical Association.

His widow, a sister and a brother survive.

SCARITO — Nicholas J. Scarito, M.D., of Lawrence, died December 3. He was in his sixty-sixth year.

Dr. Scarito received his degree from George Washington University School of Medicine in 1912. He was a member of the American Medical Association.

His widow, a son, a daughter, a grandchild and two brothers survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

VISION TESTING IN MASSACHUSETTS SCHOOL CHILDREN

Eye tests for school children are a major concern of school health departments, particularly of the school physicians. Since poor eyesight is often remediable, no child should be permitted to struggle through school for lack of attention to a visual deficiency. An ophthalmologic examination for every school child would be ideal, but since practical considerations make such a program impossible, parents, nurses and teachers can be enlisted to serve as reconnaissance groups for discovering children with visual defects. The school seems to be the agency best suited for directing a large-scale reconnaissance project of this kind.

Although lay persons ordinarily should not be expected to make diagnoses or suggest treatment, most teachers and nurses can become highly skillful in administering subjective tests and obtaining reliable test responses. By careful observation for symptoms, supplemented by a comprehensive

screening test, the school staff is in a position to detect the majority of children needing the attention of the eye specialist.

Such a test is the new "Massachusetts vision test," already serving about a third of the towns in the Commonwealth. It was designed particularly with a view toward getting a better job done in the schools and to stimulate attention to the related problem of sight conservation. It is particularly notable for the precise instructions provided for those giving the test, as care and exactness are essential in order to get good results. Since persons with special interest and aptitude in giving such tests usually obtain superior results with less expenditure of time and effort than those who labor over such work without enthusiasm, it is suggested that persons with these special aptitudes be selected for performing the tests. Whether the tester be a teacher or a nurse, she should be chosen because she excels in the easy handling of children, has a quick grasp of essential details and uses good judgment in recording a child's responses.

This new test includes a Snellen chart employing the symbol E (with the middle prong the same length as the other two), which is considered superior to the numbers or letters commonly used on vision test cards. The card is to be read at a distance of 20 feet. Illumination is standardized by means of an electric bulb arranged to give an even distribution of approximately 15 foot candles over the surface of the chart. According to the Snellen formula, the "20 line" is the critical test. Failure to read this line correctly at the 20-foot distance is interpreted as a deviation from normal, and the child who cannot read this line with either eye is therefore referred for a retest. Failing this, he is then referred to the family specialist for examination. About 90 per cent of all children picked up by the school test are found by the simple use of this modified Snellen card.

Two other checks are included in the test: one for latent hypermetropia, which employs plus (+) spherical lenses in eyeglass frames, and the other, a check of muscle imbalance. The latter makes use of a multiple Maddox rod mounted for the right eye in a spectacle frame, with no lens for the left eye. The object of fixation is a small light arranged in a simple device for describing the degree of heterophoria. These two tests are so easy for a lay person to administer that only a minute or two is required for each child. There is some controversy over the practicability of these additional tests, because some ophthalmologists refuse to correct moderate degrees of hypermetropia in children and some decline to prescribe for muscle imbalance. Experience with large numbers of cases, however, presents evidence that correction, often temporary, is often highly beneficial, especially for children with records of poor school achievement.

The test is receiving high praise from specialists who are examining school children selected by the method. Of particular interest to some of them is the fact that certain children, hitherto not detected, yet suffering from eyestrain, are being discovered, particularly those with latent hypermetropia.

MISCELLANY

GRANTS BY THE BARUCH COMMITTEE ON PHYSICAL MEDICINE

The Administrative Board of the Baruch Committee on Physical Medicine has announced the granting of an additional total sum of \$185,000, which is being given by Mr. Bernard M. Baruch for the further advancement of the program in physical medicine and the physical rehabilitation of those disabled in the war. This sum has been divided into seven grants as follows: \$50,000 to the Massachusetts Institute of Technology; \$40,000 to the University of Minnesota Medical School; \$30,000 to the Harvard Medical School; \$30,000 to the University of Southern California School of Medicine; \$15,000 to the State University of Iowa College of Medicine; \$15,000 to the University of Illinois College of Medicine; and \$5000 to the Marquette University School of Medicine.

The grants to the Massachusetts Institute of Technology and the University of Minnesota are in addition to the gift of \$1,100,000 made by Mr. Baruch in April, 1944, at which time grants were made to Columbia University College of Physicians and Surgeons, New York University College of Medicine, the Medical College of Virginia and for minor research and fellowship programs for the advancement of physical medicine.

The present gift to the Massachusetts Institute of Technology is in support of a five-year program of training and research in electronics, instrumentation and physics in relation to medicine, to be carried on under the auspices of the Department of Biology and Biological Engineering. It was the conviction of the Scientific Advisory Committee of the Baruch Committee on Physical Medicine that Baruch fellows and other physicians should have more than a superficial knowledge of the physics and technology underlying the physical methods and instrumentation used in this field, and it was suggested that training in this aspect might effectively be centered at the Massachusetts Institute of Technology. The program will be under the general supervision of Francis O. Schmitt, head of the Department of Biology and Biological Engineering and under immediate supervision of K. S. Lion, assistant professor of applied biophysics, who is an expert in physical instrumentation.

The other grants have been allocated from the fund of \$200,000 given by Mr. Baruch in April. The sum of \$30,000 was granted to Harvard Medical School for the establishment of a three-year program to provide fellowship or residencies to be used for the benefit of qualified physicians who are selected to be trained in this field. This sum will be administered by the Standing Committee on Physical Medicine, recently appointed by Dean C. Sidney Burwell of Harvard Medical School, composed of Drs. J. B. Ayer, D. Denny-Brown, W. T. Green, J. H. Means, A. L. Watkins and E. M. Landis (chairman). Appointments to the fellowships, which generally carry stipends of \$2500 or \$3000, will be made annually but may be renewed to provide up to three years of specialized study and research. Emphasis will be placed on training a few men in basic research and clinical investigation.

Unusual opportunities for clinical experience and research in the psychologic and psychiatric aspects of physical medicine will be available at Harvard. The first year will be wholly or in part devoted to basic research related to physical medicine in one of the preclinical sciences, such as physiology, anatomy or biophysics. The second year will be spent in clinical training in physical medicine at the Massachusetts General Hospital and other hospitals affiliated with the Harvard Medical School. In the third year, fellows will be

assistants in physical medicine with clinical responsibilities. For candidates with extensive previous training, one-year clinical fellowships will also be granted. Applicants must have an M.D. degree from an approved medical school and a minimum of one year of internship in an approved hospital.

PULMONARY TUBERCULOSIS AS INFLUENCED BY WARTIME RELOCATION

The danger that an unsuspected case of tuberculosis will infect others is present wherever human beings live in close contact. Whether it be in families, in schools, in offices, or under such artificial conditions as were produced by the evacuation of children from the danger areas in England is not important—the significant factor is always the case which is not recognized until too late to prevent spread of the disease. Too often children are overlooked in the search for contacts when a case of tuberculosis is discovered. The following abstract from a recent paper (Hall, M. Pulmonary tubercle in children: influence of evacuation on its incidence. *Lancet* 2:35-37, 1943) discusses the problem.

* * *

An increase in tuberculosis in England following the outbreak of the war seemed to justify collection and examination of the results of work among tuberculous children in East Sussex in relation to the spread of the disease traceable to evacuation and billeting.

Little work has been done in England on locating the source of tuberculosis observed among children. Reports from Scandinavian and American investigators show that wherever the background of these children is carefully studied, large numbers of unsuspected spreaders of bacilli can be detected among their contacts, since infection quickly registers among children exposed to open cases of tuberculosis. This has been demonstrated by our experience with evacuated children.

History, physical examination, tuberculin skin tests, blood sedimentation rates and chest x-ray films were recorded in all cases. Gastric lavage was done on cases admitted to the hospital.

Cases showing the effect of billeting healthy children with others who have open tuberculosis are as follows:

Case 1. A girl twelve years old was admitted to the hospital with a diagnosis of rheumatism. She was found to have a cough of several months' duration but previous examinations made in London had proved negative for tuberculosis. Therefore, the tuberculosis office of the reception area had not been notified. Cavities were found at both apices. This was confirmed by x-ray. The blood sedimentation rate was 21 mm., later being 50 mm.; the sputum was loaded with tubercle bacilli.

School contacts. Four children out of 15 were found to be infected with tuberculosis. Two others showed suspicious x-ray findings. All children were re-examined at three-month intervals until calcification developed in the primary foci and mediastinal nodes.

Billet contacts. A girl six years old was infected by Case 1, who was billeted with the parents of Case 2 for six months, during which time the child developed a cough. She had a pleural effusion in the right base, demonstrated by x-ray. The primary complex appeared as this cleared. The child made a good recovery, with healed calcified lesions in the right lung appearing later.

Another contact was an eight-year-old girl who was admitted to the hospital complaining of abdominal pain. She gradually developed tuberculous meningitis and died after three weeks. X-ray films showed miliary tuberculosis. She spent a month with Case 1 at a holiday camp, sharing a bed with her at this time.

Case 2. A boy eleven years old was sent to the local practitioner because he looked thin. The doctor found suspicious signs in his chest and sent him to the hospital. The school medical officer had examined this boy with special attention because his mother had died of tuberculosis but did not x-ray his chest. No note had been sent to the tuberculosis officer of the reception area. There were cavities at both apices, confirmed by physical signs. Gastric lavage showed many tubercle bacilli. In addition to the boy's mother, a brother and a sister in the same

family died with tuberculosis and the child himself had attended a tuberculosis clinic.

School contacts. In all, 40 children and their teacher were examined; 11 of them were found to have been infected with tuberculosis; 6 of these showed definite activity, 4 had healing lesions and 1 had a calcified lesion.

Billet contacts. Case 2 was billeted with 5 other children, 3 of whom became infected with tuberculosis. One child in this group had sanatorium treatment.

The effect of billeting healthy children in households in which there is or has been tuberculosis is no less serious, as is illustrated by the case of a child of five who entered the hospital with phlyctenular conjunctivitis and was found to be infected with tuberculosis. She was one of six brothers and sisters, all previously healthy, who were placed with a foster-mother known to have had tuberculosis eight years previously. This woman had a bad cough while the children were living with her but refused examination. Four of the six children were found to have tuberculosis.

Neglecting the examination of child contacts may also have disastrous results, as is shown by the following case:

Case 3. A girl six years old died in the hospital of miliary tuberculosis. The child was infected by her aunt, a young adult who had entered a sanatorium some months before. The child had often visited her but had not been examined, and the tuberculosis officer in the reception area had not been notified.

School contacts. Case 3 attended an evacuation school and all the children, 39 in number, and 3 teachers were examined. Eight children had evidence of recent tuberculous infection.

Two of the children examined with this school were also found to have tuberculosis. The infection in the case of these two was traced to their mother, who had died from tuberculosis four months earlier. After the death of the mother one child had been examined clinically but no x-ray films were taken.

Billet contacts. A brother and a cousin, the latter of whom died of tuberculous meningitis, were found to be infected. Another brother remained healthy.

In reviewing these cases one is impressed by the importance of the search for child contacts and the little attention usually paid to them. So great is the risk of bacillary transmission that all children who have been in close or repeated contact with a case of reinfection pulmonary tuberculosis should be regarded as having become infected until it is proved otherwise.

To be domiciled with a case of open phthisis is relatively much more dangerous than to attend the same school with a case. Physical examination that deals with the exterior of the chest alone is worthless in children and may be dangerous, as an infected child may be labeled as "normal." All child contacts should have complete examinations, including tuberculin tests and x-ray examinations.

Wherever children are placed in a new environment, great care should be taken to establish that they are not suffering from tuberculosis and that they are not thrown unwittingly into contact with it. Certainly, a more intensive search must be made for all child contacts of open cases of tuberculosis. — Reprinted, with changes, from *Tuberculosis Abstracts* (December, 1944).

ELLA SACHS PLOTZ FOUNDATION

During the twenty-first year of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation, twenty-seven applications for grants were received by the trustees, nineteen of which came from the United States, the other eight coming from five different countries in Europe, Asia and South America.

In the twenty-one years of its existence the Foundation has made five hundred and eight grants which have been distributed to scientists throughout the world.

In their first statement regarding the purposes for which the fund would be used, the trustees expressed themselves as follows:

For the present, researches will be favored that are directed toward the solution of problems in medicine and surgery or in branches of science bearing on medicine and surgery.

As a rule, preference will be given to researches on a single problem or on closely allied problems; it is hoped that investigators in this and in other countries may be found, whose work on similar or related problems may be assisted so that more rapid progress may be made possible.

Grants may be used for the purchase of apparatus and supplies that are needed for special investigations, and for the payment of unusual expenses incident to such investigations, including technical assistance, but not for providing apparatus or materials which are ordinarily a part of laboratory equipment. Stipends for the support of investigators will be granted only under exceptional circumstances.

In the past few years the policy outlined in the second paragraph has been neglected and grants will be given in the sciences closely related to medicine without reference to special fields. The maximum size of grants will usually be less than \$500.

Applications for grants to be held during the year 1945-1946 must be in the hands of the Executive Committee before April, 1945. There are no formal application blanks, but letters asking for aid must state definitely the qualifications of the investigator, an accurate description of the research, the size of the grant requested and the specific use of the money to be expended. In their requests for aid, applicants should state whether or not they have approached other foundations for financial assistance. It is highly desirable to include letters of recommendation from the directors of the departments in which the work is to be done. Only applications complying with the above conditions will be considered.

Applications should be sent to Dr. Joseph C. Aub, Massachusetts General Hospital, Fruit Street, Boston 14.

CORRESPONDENCE

FUTURE OF MEDICINE

To the Editor: The article "Justice and the Future of Medicine" by Wendell Berge, published in the November 30 issue of the *Journal*, is a thought-provoking presentation of the problem of social medicine that should be read and pondered by every doctor.

Good health is both an individual and a community asset. The prosperity of a community may, with reason, be said to depend on its health.

Medical knowledge regarding preventive, diagnostic and curative procedures has ranged far ahead of the application of this knowledge. With the improvement of medical procedures the cost has increased.

Within limits, both private and public health can be purchased, provided the cost of applying known medical measures can be met. Medical economics is the study of how to obtain the best medical care and protection for the greatest number of people at the lowest possible cost and in the most satisfactory manner. In spite of the great accomplishments of medicine it cannot be denied that the people want something more.

Mr. Berge suggests: "If an instrument of common health can be provided on terms the people can afford the people will rejoice. If you do not help them to it the people will seize whatever agencies are at hand as a help in need. For the universal demand that the common health be served cannot much longer be delayed."

If there is a lesson to be learned from Mr. Berge's article, — and I think there is, — it is that doctors should play a leading part in shaping this "instrument of health" and in the development of all medical measures; they should not only insist on the provision of the highest quality of medical care but also guide in other ways. Scientific advancement is always needed, but practical and universal application of these advances are equally important.

A sound health program must be founded on sound basic principles and policies. As a constructive addition to the study of this vital problem of medical economics, I enclose a summary of "Principles of a Nation-Wide Health Program," which is a detailed report prepared by the Health Program Conference. Every doctor should read the full

report carefully and without prejudice and then consider what he, personally, should do about it.

NATHANIEL W. FAXON, MD

PRINCIPLES OF A NATION-WIDE HEALTH PROGRAM*

This program and these principles are the joint product of twenty-nine men and women of differing interests: thirteen physicians, some in private practice and others in universities, health agencies and hospital administration; six economists, a majority of whom have long studied and worked for health insurance; the research directors of the American Federation of Labor and the Congress of Industrial Organizations; and eight administrators connected with voluntary or governmental agencies. The problems of dentistry, nursing and pharmacy have not thus far been considered.

Under the program that the Conference proposes, the medical services would be comprehensive. Plans of medical care of a community that are limited to hospitalization, surgery or "catastrophic illness" are helpful and should be encouraged, but they cover only a part of the medical needs. Plans that provide only cash payments to meet the cost of services, in whole or part, are not desirable because such cash payments may be used for other purposes. Only comprehensive preventive, diagnostic and curative service will minimize disability, inefficiency and premature death, which bring heavy losses not only to individuals but to productive industry and agriculture.

The program should cover all or most of the population. In the opinion of the Conference, limitation of coverage to certain income groups or to those engaged in certain occupations would not be satisfactory. Those who wish to purchase medical care outside of the national health system should be free to do so.

In order that comprehensive service shall be available to all or most of the population and in order to minimize the administrative costs of acquiring members, it is essential that financial participation in the system be compulsory, provided that, as we have said, those who wish to purchase comparable medical care outside of and in place of a national health system should be free to do so. American families ordinarily spend directly about 4 per cent of their earnings for all kinds of medical services. Of this, the expenditures for physicians and for hospital services constitute about three fourths, that is, about 3 per cent of the annual income. The American people are now spending for physicians' services and hospitalization enough to make it possible to provide adequate medical care for all, with only minor supplementation.

The insurance principle applied to medical expenditures will mean no greater expenditure of money but should result in better medical care, regularizing existing payments rather than imposing new burdens. The expense of physicians' and hospital services would be met by a national system of contributory health insurance, supplemented by taxation. We recognize that there must be a certain amount of federal direction, but administration must be decentralized on a state basis, recognizing voluntary as well as governmental agencies. The quality of care and the status of the medical profession should be fostered by improved professional organization of service, by retaining the freedom-of-choice principle, and by adequate compensation and educational opportunities.

The amounts of payment from employees and self-employed persons should be related to the earnings of the contributors. It is generally considered that it is desirable that employers should also contribute. Because of the inadequate provision of hospitals and other medical facilities in some parts of the country, particularly in rural areas, capital funds for such facilities are necessary "which, insofar as unavailable from nongovernmental sources, should be provided by federal, state or local taxation, or combinations of these."

The national health program should include general tax funds from the start, especially to aid in the construction

*A summary of a report published for the Health Program Conference by the Committee on Research in Medical Economics, 1790 Broadway, New York 19, New York.

and operation of new or improved hospitals or health centers, particularly in rural areas, in the further extension of full-time public-health departments, in the application of preventive measures made available in every part of the country and in the provision or improvement of medical services to those dependent on and other persons not directly covered by the insurance system.

The report is not a draft of legislation. It sets forth policies and principles, including those of organization, and does not specify the governmental agencies to be involved. Participation between the profession and the public is emphasized throughout. The people cannot obtain a high quality of service unless adequate training, intellectual freedom and economic security are assured to physicians.

The national policy-determining body for the administration of a health program must be composed of representatives of the chief groups of those who receive service and of those who furnish it. Similar policy-determining bodies should be organized at local and intermediate levels. All policy-determining bodies should be responsible to the interest of the general public, as distinguished from the interest of any vocational or economic group.

The administrative officers working under such public bodies should be removed as fully as possible from partisan political pressures and should fall into two operating groups: professional and financial. The strictly medical activities should be under qualified members of the profession. Financial responsibilities should be placed under the control of a financial group. Both the professional and financial officials, each having administrative authority in their respective fields, would be co-ordinated through the policy-determining body. Thus, when the decisions had to do with medical considerations only, they would be made by the medical administrators aided by advisory councils of physicians. When decisions related to general policies they would be made by a joint group representing both the profession and the public. These principles would apply to each local area, as well as on national and intermediate levels.

The administration of services should be decentralized, with "responsible participation of local physicians and agencies (governmental and voluntary) in the administration and control of their health services under national standards; the funds and administrative agencies of local subdivisions and of the states might well be utilized in planning and in the provision of services." The local organization "should be the administrative unit and the foundation of the national system."

Voluntary hospitals with their extensive facilities would continue under the system, maintaining their autonomy; and voluntary health-insurance plans would also be recognized. "Voluntary agencies providing services of acceptable standard should have the right to participate in the system. Voluntary agencies not providing services should have the right to participate if they contribute to the efficiency and economy of the system. Under these principles, voluntary agencies which directly provide physicians' services or hospitalization of acceptable standards would be eligible to participate in the system, but agencies would not necessarily be included when they were concerned only with the collection of funds and the distribution of cash indemnities to beneficiaries."

In order to maintain and improve the quality of service, the career of a physician must offer stimulating professional opportunities and adequate financial compensation. There must be ample support for medical education and research: freedom of experimentation in medical science, medical technology and in the different types of medical practice. Group medical practice is to be encouraged. The organized staffs of the best hospitals and clinics now constitute the most widely diffused examples of group medical practice. Unfortunately, the advantages of group practice in these hospitals are at present not universally achieved for all classes of patients, often being limited to those in the low income brackets, the so-called "ward patients." Hospitals and clinics should be reorganized, as some of them have already been, so that comprehensive service through group medical practice will become available to people of all incomes. As medical centers, it is possible that hospitals may ultimately provide preventive, diagnostic and therapeutic services for bed, ambulatory and home patients, and also office facilities for the physicians on their staffs.

In the full report, certain principles regarding the payment of physicians are stated. "Compensation should be adequate." The other principles relate to judging adequacy of income and to fixing the best method of payment under various circumstances. Fee-for-service payment has been the long-accepted method of payment in spite of certain disadvantages. Alternative principles stated in the report would permit fees for service, but "would tend to encourage the compensation of general practitioners by the capitation or the salary method."

How would the method of payment be decided? In each local area the general practitioners carrying on private practice would determine by majority vote the method of payment that they preferred, but "those physicians who wished to carry on group instead of individual practice in the same area, and to be remunerated accordingly, would also be protected in their right to do so." Specialists, qualified under standards set by professional bodies, would be paid on a fee or a salary basis according to local arrangement. The incomes of hospitals under a nation-wide health program would be mainly derived from services rendered to beneficiaries of the program. Consequently, payments from the health-insurance fund to the hospitals must be adequate to support high-quality service. Here and elsewhere, the full report develops many of the items in more detail.

The basic "principles of freedom" for the people and for physicians must be assured. People "should be entitled to choice among individual physicians, organized groups of physicians, hospitals, clinics and any other agents, agencies or service recognized under the law; and also to change their sources of service when they so desire, under reasonable regulations." Physicians, on their part, should have "the right to accept or reject patients; the right to participate or not to participate in a publicly established system; the right to be represented in negotiations through organizations of their own choosing; and the right to furnish services as individuals, or to organize medical groups, or to associate themselves with existing medical groups or hospitals which will accept them."

The program based on these and the preceding principles was developed by the Conference in "the belief that there is now need for public action to make adequate medical care more widely accessible to the American people and to improve the quality, organization and economy of medical services."

BOOK REVIEWS

To the Editor: Is there something wrong with the Book Review Section of the *Journal*? We admit this is rather a bold question but nevertheless a serious one.

At the beginning of 1943 a book *The Inner Ear* by Joseph Fischer and Louis E. Wolfson was sent to many leading medical journals, including the *New England Journal of Medicine*, *Journal of the American Medical Association*, *Archives of Otolaryngology*, *Annals of Otolaryngology*, *Laryngoscope*, *War Medicine*, *Lancet* and so forth. Without exception the reviews were highly favorable, and the general trend of comment was that the book filled a long-felt want. All the journals, with the exception of the *New England Journal of Medicine*, published their reviews of this book promptly and more than one year ago. The book review in the *New England Journal of Medicine* was published in the October 12, 1944, issue, more than one year after all the other reviews had appeared. This review commented only on the first two chapters and was most unfavorable. The statement was also made that in the coming second edition (about which the authors have no knowledge) the reviewer expected improvement.

We believe that the editors of the Book Review Section of the *Journal* could well re-read, with profit, the letter of Dr. Frank H. Lahey in the *Journal* of November 4, 1943, in which he particularly emphasized the desirability that the reviewer be a qualified critic and that his criticism should not be colored by personal prejudice. The letter of Dr. Henry A. Christian in the *Journal* of March 2, 1944, is also pertinent in that he gives some very good reasons in favor of signed book reviews.

*Further study should be given to a supplementary method of payment for the minority other than that determined by the majority.

Surely there must be something wrong when the *New England Journal of Medicine* reviews a book more than a year after all the other medical journals mentioned above, all of them having received the book at the same time. The complete lack of agreement of the *Journal's* review with those of the other periodicals can of course not be commented upon, but it raises questions as to the correctness of the reviewer's opinions as expressed in the *New England Journal of Medicine*.

BOOK REVIEWS

Medical Diagnosis: Applied physical diagnosis. Edited by Roscoe L. Pullen, M.D. With a foreword by John H. Musser, M.D. 8° cloth, 1106 pp., with 584 illustrations and 12 colored plates. Philadelphia and London: W. B. Saunders Company, 1944. \$10.00.

This book is intended to develop the ability of the physician to examine all parts of the body. Specialists have contributed chapters outlining the procedure appropriate for examinations within their special provinces.

This plan is excellent for an encyclopedia but has certain disadvantages when the material is compressed into a single volume intended for use as a textbook. One is tempted to ask why, if one man is expected to master the contents of the text, should not one man write it, thereby demonstrating the possibility of a single person's mastering the field covered by the book. Again, as a textbook, it is too advanced for the second-year student, who has not yet been introduced to much of the subject matter, whereas more detailed information is preferable for advanced or graduate students. Probably a physician or student is best equipped when he has mastered the fundamentals of simple physical diagnosis and then uses special manuals of electrocardiography, ophthalmology, gynecology, dermatology and so on for assistance in special fields.

Nevertheless, the work is as well done as one can reasonably demand, and its value is likely to be determined by the extent to which it is chosen by instructors and students.

Principles and Practices of Inhalational Therapy. By Alvan L. Barach, M.D. 8°, cloth, 315 pp., with 59 illustrations. Philadelphia: J. B. Lippincott Company, 1944. \$4.00.

This is an unusual book in that it represents in the main the studies of the author over a period of twenty-four years on the therapeutic use of gases in clinical medicine, comprising the results of over a hundred papers. It will be remembered that in 1925 Dr. Barach developed an oxygen tent ventilated by the passage of air over ice, which first provided a hygienic atmosphere in respect to temperature and humidity, as well as an effective concentration of oxygen. He introduced helium as a therapeutic gas in the treatment of asthma and obstructive dyspnea and, with the aid of skilled technical assistants, developed chambers, hoods and masks for the administration of oxygen and of helium and oxygen mixtures. His use of positive pressure in the treatment of obstructive dyspnea and pulmonary edema brought a new therapeutic procedure to clinical medicine. Of great interest is his method of immobilizing both lungs through equalizing the air pressure on the inner and outer surface of the chest wall; this equalizing pressure chamber has been employed on patients with advanced pulmonary tuberculosis with promising results.

A good description of the contributions of other workers in this field is included, together with an extensive bibliography.

The book describes in clear detail the use of oxygen, helium, carbon dioxide, positive pressure, continuous pulmonary arrest and vaporized solutions of epinephrine, Neo-Synephrin and sulfonamides as therapeutic agents for maintaining respiratory function. It is well illustrated with photographs of apparatus and with charts confirming the physiologic usefulness of various types of inhalational therapy.

Each chapter heading represents a disease entity, for example, pneumonia, pulmonary edema, bronchial asthma, shock, acute altitude sickness and so forth, and contains a discussion of the pathologic physiology, the specific inhalational therapy and the results to be expected. The chapters covering bronchial asthma, congestive heart failure, pulmonary emphysema and chronic pulmonary tuberculosis are beautifully written

and replete with the special disturbances in respiratory function involved and their management. Those interested in aviation medicine will find the chapter on acute altitude sickness, including many of the author's own observations, one of the best ever written on this timely subject.

This is the first complete textbook of its kind. The physician who wishes to understand the physiologic basis and technic of inhalational therapy will find it indispensable. To the student and research worker in the field it will serve as a bible, as well as a source of stimulation in the study of this fascinating, relatively new approach of therapy via the pulmonary route.

ANNOUNCEMENT

Dr. Oscar J. Marcil announces the removal of his office from East Jaffrey, New Hampshire, to 66 Parker Street, Gardner, Massachusetts.

BARUCH FELLOWSHIPS IN PHYSICAL MEDICINE

The Harvard Medical School announces fellowships in physical medicine supported by grants from the Baruch Committee on Physical Medicine. The purpose of these fellowships is to provide a three-year training for academic and clinical careers in the field of physical medicine. They are granted annually but subject to renewal for a total duration of three years. The first year will be wholly or in part devoted to basic research related to physical medicine in one of the preclinical sciences, such as physiology, anatomy or biophysics. The second year will be spent in clinical training in physical medicine at the Massachusetts General Hospital and other hospitals affiliated with the Harvard Medical School. In the third year fellows will be assistants in physical medicine with clinical responsibilities. For candidates with extensive previous training, one-year clinical fellowships will also be granted.

Applicants must have an M.D. degree from an approved medical school and a minimum of one year of internship in an approved hospital. The annual stipend will be \$2500 (single) or \$3000 (married). Applications may be obtained from the Dean, Harvard Medical School, 25 Shattuck Street, Boston 15, Massachusetts.

JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston
Lecture Hall, 9-10 a.m.

MEDICAL CONFERENCE PROGRAM

Wednesday, January 3 — Surgical Difficulties in Ulcerative Colitis. Dr. Francis Moore.

Friday, January 5 — Cancer of the Cervix. Dr. B. Lorincz.
Wednesday, January 10 — The Incidence of Psychoneurosis in the Medical Clinic. Dr. Joseph Kaplan.

Friday, January 12 — Cancer of the Pancreas and Ampulla Relative to Diagnosis and Resection. Dr. Richard B. Cattell.

Wednesday, January 17 — Breast Cancer: Problems of diagnosis and treatment. Dr. Joseph Tartakoff.

Friday, January 19 — The History and Physical Examination of the Gynecological Patient. Dr. Louis E. Phaneuf.

Wednesday, January 24 — Studies of Finger Capillaries in Neuroses, Epilepsy, and Migraine. Dr. Alfred Hauptmann.

Friday, January 26 — The Treatment of Thyrotoxicosis with Anti-thyroid Drugs. Dr. R. Williams.

Wednesday, January 31 — A Recent Advance in Dermatological Therapy. Dr. Francis M. Thurmon.

On Monday mornings clinics will be given by Dr. Samuel Proger. On Tuesday and Thursday mornings Dr. S. J. Thannhauser will give medical clinics on hospital cases. On Saturday mornings clinics will be given by Dr. William Dameshek.

THE CAUSE OF DEATH IN DIABETES*

A Report of 307 Autopsied Cases

STANLEY L. ROBBINS, M.D.,† AND ARTHUR W. TUCKER, JR., M.D.‡

BOSTON

A SEARCH through the literature for an answer to the question of the causes of death in diabetic patients reveals a large amount of available material, with surprisingly little of it based on pathological confirmation through autopsy examination. Analyses based on clinical findings alone and on diagnoses found on death certificates are filled with patent inaccuracies. Joslin¹ and others have repeatedly demonstrated that figures gathered from death certificates are subject to so many errors as to vitiate many of the conclusions drawn from them. The example of a cerebral hemorrhage found at autopsy as a cause of death in a case clinically diagnosed as a diabetic coma is a not infrequent occurrence. This report therefore represents an attempt to determine the causes of death in a series of diabetic patients from a strictly anatomic approach, comparable to the series of 486 diabetic autopsies reported by Warren.² It is believed that such statistical analyses based on anatomic findings give more accurate information regarding causes of death than do analyses based solely on clinical observations.

MATERIAL AND METHODS

The subject matter of this report is drawn from a study of 307 diabetic patients autopsied at the Mallory Institute of Pathology during the years 1932-1942, inclusive. Excluded from the study are a few cases in which the material was inadequate. In each case the complete protocol was reviewed and the available histologic material was examined to establish the anatomic cause of death. When more than one possibility presented itself, the clinical records were reviewed in an effort to understand more clearly the patient's terminal course. It is obvious that cases were met with in which no clear-cut conclusion could be drawn, either because of inadequate records or because of the fundamental

limitations of the anatomic approach. Such cases were discarded. The patients included 131 males and 176 females, ranging between the ages of thirteen and eighty-four.

As a basis for comparison, the anatomic causes of death in approximately 2800 autopsied nondiabetic patients were summarized. The control group represented all nondiabetic patients over twelve years of age coming to autopsy in the years 1936, 1937, 1941 and 1942, whole years being selected to avoid seasonal variations. These particular years were selected in an effort to represent both the pre-sulfonamide and post-sulfonamide eras, as well as changing therapies over the period of investigation.

Adequate histologic material was available in 268 of the diabetic cases. Routine sections of the liver, kidneys, pancreas and adrenal glands were studied in an effort to determine the frequency of specific histopathologic changes associated with the diabetes.

RESULTS

Table 1 indicates the distribution of the causes of death in the diabetic and control series. These various groups and subgroups were selected because they obviously represent the most frequent conditions of which diabetic patients — and for that matter nondiabetic ones — die. Certain of the headings used require a few words of explanation to clarify the type of case included within the category.

The term "peripheral vascular disease" is used to indicate the cases of vascular insufficiency leading to gangrene and death, either without infection or with infections so trivial as to constitute only a minor part of the clinical picture. In many of these cases, amputation was performed and was followed at some interval of time by death. If there was a clear-cut chain of circumstance pointing to the peripheral vascular disease as the initiating event in the fatal course, the death was listed in this category. On the other hand, infections of the extremities were separated from the above group because

reactions, often with spreading sepsis, septicemia and death.

The term "pulmonary infection" indicates a wide variety of inflammatory diseases of the lung, such as bronchiectasis, lung abscess, pneumonia and tuberculosis, no attempt being made to separate this heterogeneous collection into its component parts.

In the interests of simplicity, unknown causes of death, traumatic deaths, anemias and a diversity of the less frequent fatal diseases have been grouped under the heading "other causes."

The most frequent cause of death in the diabetic group was pulmonary infection (25.6 per cent); cardiac decompensation and coronary occlusion follow with 12.3 per cent and 10.8 per cent, respectively. The relative frequency of fatal carcinoma is seen to be 8.4 per cent. That of acute pyelonephritis, decompensated, was 7.3 per cent, and that of uncomplicated coma 7.2 per cent. Cerebral vascular disease was found to be relatively low in the scale, accounting for only 5.2 per cent of the deaths.

In the control group pulmonary infection again led with 24.2 per cent. Deaths due to carcinoma were second with 14.7 per cent. Cardiac decompensation followed with 12.6 per cent, whereas coronary occlusion and acute pyelonephritis were significantly far down on the list, with 4.2 and 1.6 per cent, respectively.

Table 2 indicates the frequency of certain histopathologic changes in the diabetic group. These lesions were arbitrarily designated as + to + + + +, only changes of ++ or greater being considered

significant. Evidence of cirrhosis was found in 27 of the 268 cases; the type was alcoholic cirrhosis in 13, biliary cirrhosis in 11, and healed acute yellow atrophy in 3.

Finally, as has been shown before,^{3, 4} the average age at death of the diabetic patients in this series was not significantly different from that of the non-diabetic, being 59.6 years in the former and 59.8 years in the latter.

DISCUSSION

In considering the figures presented, one must bear in mind that they are derived from a large municipal hospital, accepting all varieties of cases, many already in terminal or near-terminal stages, together with emergency cases combed from a wide metropolitan area. For example, the apparent high incidence of pulmonary infection as a cause of death as compared with that in other series is due in part to the fact that the hospital annually receives a significant number of cases of pulmonary tuberculosis. In the diabetic group, 17 of the 73 fatal pulmonary infections were tuberculous, representing a frequency of 5.6 per cent or 6.0 per cent when corrected for coma. A comparison with the 8 per cent incidence found in the control group reveals no significant difference between the two groups. Similarly, deaths from coma (7.2 per cent) occupy

a higher rank in the causes of death in the present series than that found in other published series because some of the patients were not infrequently first seen in far-advanced coma at a stage in which the process had perhaps become irreversible.

On the other hand, the relatively low incidence of coronary occlusion as a cause of death (10.8 per cent) may be in part attributable to two factors. In the first place, in this laboratory the assignment of coronary occlusion as a cause of death is not made unless the myocardial infarction is significantly large, or unless there is a clear-cut terminal clinical course that corroborates the finding of an occluded coronary artery in cases in which the process has been too recent for the development of a massive infarction. In the second place, a certain percentage of acute coronary deaths are handled by the Medical Examiner's Office and hence are not available for inclusion within this series.

Perhaps worthy of emphasis is the finding of a relatively similar incidence of cerebrovascular accidents as a cause of death in the diabetic and nondiabetic groups — 5.2 per cent and 7.5 per cent, respectively. This finding is in agreement with that of Root and Sharkey,⁵ who state that the non-vascular cerebral arteries have no greater predisposition to atherosclerosis in diabetic than in nondiabetic patients.

A point of further interest is that there was a lower incidence of death from carcinoma in the diabetic group (8.4 per cent) than in the control group (14.7 per cent). In view of the close similarity of the survival age in the two groups, age does not seem to aid in accounting for the difference, and at present no other factor appears to be implicated. It is particularly noteworthy in view of the present interest in the relation of cholesterol and of hypercholesterolemic states to the production of neoplasia. A comparison of the figures reveals other significant differences in only four categories, namely, coronary occlusion, peripheral vascular disease, acute pyelonephritis and infections of the extremities.

Considering each of these separately, one finds that coronary occlusion was two and a half times as frequent in the diabetic group as in the control group. Peripheral vascular disease, although a rarity among nondiabetic patients, accounted for 1.5 per cent of the deaths among diabetic patients, which confirms a well-known fact previously emphasized. A similar situation obtains with reference to infections of the extremities, in which the admonitions of Joslin⁶ are borne out by the greater frequency with which this complication leads to death among diabetic patients than among nondiabetic ones. Finally, renal infection, which for many years has been considered a minor complication, is seen to be a relatively important cause of death in the diabetic group. Acute pyelonephritis was four and a half times as frequent a cause of death in the diabetic group as in the control group, and moreover ranks sixth among the causes of death in the former group.

The six most frequent causes of death in the two groups are listed in Table 3.

In Warren's series of 486 autopsies on diabetic patients who died during the years 1924–1937, in-

cerebral arteriosclerosis accounted for 4 per cent of the deaths. The percentage of patients dying of pulmonary infections was 10 per cent, with pyelonephritis occupying a low place on the list of total causes, accounting for only 2 deaths.

In an evaluation of the histologic material presented in Table 2, it can be seen that each of the findings is relatively inconstant. Not only were most of the histologic changes haphazard in their occurrence, but all save one were nonspecific from a diagnostic standpoint.

At this laboratory, only glycogen nephrosis or so-called "Armanni-Ebstein cells" in the tubular epithelium of the loops of Henle are considered diagnostic of diabetes mellitus. It is noteworthy that this change was evident to a significant degree in only 42 per cent of the cases. It may be of some interest to note that with the passing years the finding of glycogen nephrosis has become increasingly less frequent, suggesting that adequate therapy may prevent this type of secondary lesion. Inter-capillary glomerulosclerosis was present in only 20 per cent of the cases.

Although nuclear changes of the liver cells were the most frequent histologic feature, occurring in 66 per cent of the series, the complete nonspecificity of such changes lends them little significance.

During the eleven years covered by this survey, 45 cases of pigment cirrhosis were autopsied. These cases are not included in the diabetic group inasmuch as the diabetes associated with this disease is considered by all the standard classifications of disease as an entity distinct from diabetes mellitus. Included in the 268 cases studied microscopically, however, were 27 cases with incidental cirrhosis, apparently only coincidental with and in no way specifically related to the diabetes.

It should be re-emphasized that the average age at death of the diabetic patient is almost precisely the same as that of the nondiabetic one. He lives as long today as the latter, but, as brought out by this survey, there are specific hazards that the diabetic patient is more likely to encounter than the nondiabetic, namely, coronary occlusion, peripheral vascular disease, infections of the extremities and acute pyelonephritis.

SUMMARY AND CONCLUSIONS

An analysis of the causes of death in 307 diabetic patients over the age of twelve, as determined by autopsy findings, is presented.

For purposes of comparison, the autopsies on approximately 2800 consecutive nondiabetic patients were reviewed for anatomic causes of death.

Adequate histologic material available in 268 of the patients in the diabetic group was reviewed to evaluate the frequency of histopathologic changes in diabetes.

From the study, several clinical impressions were confirmed. The diabetic patient lives as long as the

a higher rank in the causes of death in the present series than that found in other published series because some of the patients were not infrequently first seen in far-advanced coma at a stage in which the process had perhaps become irreversible.

On the other hand, the relatively low incidence of coronary occlusion as a cause of death (10.8 per cent) may be in part attributable to two factors. In the first place, in this laboratory the assignment of coronary occlusion as a cause of death is not made unless the myocardial infarction is significantly large, or unless there is a clear-cut terminal clinical course that corroborates the finding of an occluded coronary artery in cases in which the process has been too recent for the development of a massive infarction. In the second place, a certain percentage of acute coronary deaths are handled by the Medical Examiner's Office and hence are not available for inclusion within this series.

CLINICAL COURSE

By far the most frequent history was one of sudden onset one day before admission; this was present in 42 cases (59 per cent). In 18 cases the onset occurred two days before admission, in 10 cases three days before admission, and in 2 cases more than four days.

The chief complaint on admission was persistent and often projectile vomiting in 46 cases (64 per cent), headache — either as a principal or a secondary complaint — in 23, stiff neck in 12, a rash in

FIGURE 2. Age Distribution.

10, and drowsiness in 10. The other chief complaints were as follows: convulsions (8 cases), fever (7 cases), delirium (7 cases), abdominal pain (4 cases), arthralgia (3 cases), myalgia (2 cases) and coma (2 cases).

In 59 cases (82 per cent) a rash was observed on admission. This appeared to be one of the most distinctive features of the disease. The skin eruption was purpuric in nature, resembling the so-called "flea-bite." These petechial hemorrhages occurred very early in the course of the disease, and in many cases multiplied rapidly within a short space of time. They usually appeared on the arms and legs, especially about the ankles. In one case the lesions were maculopapular, resembling the rash present in measles. The diameter of the hemorrhages varied from pinhead size to 3 or 4 cm., the larger ones having necrotic centers. A characteristic of this eruption was the occurrence of the petechial hemorrhages in the mucous membranes of the mouth and eyes, and also on the skin of the palms and soles. This fact was helpful in diagnosing the disease in Negroes, whose skin is lighter on the palms and soles than on the rest of the body, making the eruptions easy to detect.

The cause of this petechial rash is believed to be small, septic, vascular thrombi that form in the small capillaries, causing extravasation of blood into the surrounding tissue.^{13, 14} The organisms can be cultured from these spots and can also be directly visualized by the technic outlined by Tompkins.¹⁵

There has been some speculation why the meningococcus has a predilection for the skin and — in the case of the Waterhouse-Friderichsen syndrome — the adrenal glands. Sacks¹⁶ thinks that the meningococcus has an ectodermal tropism that accounts for this. In most cases the hemorrhages faded appreciably within twenty-four hours after treatment and in three days little residual discoloration remained on the skin.

Convulsions were limited almost entirely to patients under three years of age. They occurred in 10 of the 14 one-year-old children, in 4 of the 12 two-year-olds, and in 2 of the 7 three-year-olds. Of the patients over the age of three, only one had a convulsion — a girl of twelve who was treated empirically at home for three days, was admitted in a moribund state and died shortly thereafter.

All the children over one year of age with evidence of meningeal infection had positive meningeal signs, but in most infants no such signs could be elicited. The patients most difficult to evaluate were those less than one year old, apparently because a slight spasm of the muscles is often difficult to detect. A more reliable index is the tension of the anterior fontanelle, which directly reflects the intracranial pressure.

Ten children were drowsy on admission, but only 2 were comatose. Hyperesthesia was present in almost all cases, and in many of them was so severe that the patient objected to any movement of the bed sheets or change in position. Myalgia and arthralgia were frequent complaints on admission. One patient had had such prominent joint symptoms that he was referred to the hospital with a diagnosis of rheumatic fever. Fifty-six patients (77 per cent) were admitted with a temperature of over 102°F.

The Waterhouse-Friderichsen syndrome is characterized by the fulminating onset of a petechial or purpuric skin eruption, a peculiar dyspnea and cyanosis and profound peripheral circulatory collapse.¹⁴ Death usually ensues after a short period of illness. Bilateral adrenal hemorrhage is found at autopsy, and is believed to be the cause of this condition. Nine patients (12 per cent) presented this symptomatology. Of these, 4, one of whom had a meningococcemia, eventually recovered after intensive treatment. Of the 5 patients who died, 2 had meningococcemia. Evidence of adrenal hemorrhage was found in the 3 fatal cases that were autopsied.

In the total series there were 6 deaths, a mortality of 8 per cent. This figure should be qualified, since 5 of these patients were admitted in a moribund state and lived only thirteen hours or less under treatment. As previously mentioned, 5 of the fatal cases showed symptoms similar to those described as the Waterhouse-Friderichsen syndrome. The other patient, although in coma, was neglected at home

nondiabetic. There are, however, certain hazards that he is seemingly more likely to encounter, namely, coronary occlusion, peripheral vascular disease, infections of the extremities and acute pyelonephritis.

We are indebted to Professor G. Wadsworth, of the Massachusetts Institute of Technology, for statistical analyses of the figures.

MENINGOCOCCAL MENINGITIS AND MENINGOCOCCEMIA IN CHILDHOOD*

A Statistical Study of Seventy-Two Cases

JOSEPH OSBORNE, M.D.,† WILLIAM H. ARNONE, M.D.,‡ AND GEORGE I. LYTHCOTT, II, M.D.§

BOSTON

MENINGOCOCCAL meningitis, also known as spotted fever or cerebrospinal fever, first accurately described in 1805 by Vieusseux,¹ is always more prevalent during time of war than in peacetime. During World War I, 5839 cases occurring in the armed forces resulted in 2279 deaths, a mortality of 39 per cent.² Judging from reports in the recent literature, two facts are apparent: first, that the high incidence of this disease is being repeated, and second, that the use of the sulfonamide drugs has greatly reduced the mortality.^{3, 4} Concurrent with the increase of meningococcal meningitis among the military population is an increase among civilians, including children.⁵

During 1943, on the Pediatric Service of the Boston City Hospital, there was a marked increase in the number of children, all under twelve years of age, having meningococcal meningitis or meningococcemia. It seemed that a review of these cases would bring attention to the prevalence of this disease among the younger population and would be valuable to those engaged in the treatment of children with this type of infection.

ETIOLOGY

The etiologic agent of this disease is the meningococcus, which was discovered by Weichselbaum in 1887.⁶ There are several strains of meningococci that can be demonstrated by immunologic reactions. Gordon and Murray⁷ originally described four serologic types, but it is now generally conceded that the majority of pathogenic strains fall into Types 1, 2 and 2a. The typing is achieved by mixing the meningococcus with type-specific serum⁸ and noting the resulting capsular swelling or agglutination.

The question how the organism enters the body is still a matter of dispute. Some observers have postulated that the meningococcus invades the central nervous system by way of the cribriform plate.⁹ The most widely accepted theory, however, is that the bacteria penetrate the mucous membranes of the nose and nasopharynx before entering the blood stream.^{10, 11}

INCIDENCE

As shown in Figure 1, the seasonal peak was reached during the spring and late fall, with a drop

FIGURE 1. Monthly Incidence.

during the summer. This coincides with the seasonal incidence of upper respiratory infections.

The disease was somewhat more prevalent among girls than among boys, the respective numbers of cases being 40 and 32.

Fourteen cases (19 per cent) occurred in those under one year of age, the youngest patient being nineteen days old, and 41 (56 per cent) in those under five years of age (Fig. 2). This coincides with the report of Holt and McIntosh,¹² who noted a high incidence of the disease in those under five years old.

§Assistant resident physician, Boston City Hospital.

tients were afebrile one week after treatment, and 36 reached a normal temperature and a general feeling of improvement in four days (Fig. 3).

COMPLICATIONS

Arthritis was the most frequent complication encountered, 9 cases (12 per cent) showing evidence of it. This is a somewhat higher incidence than was

FIGURE 3. Morbidity.

reported in Boulduan's series cited by Schein,²⁰ in which 13 of 169 patients (7.7 per cent) manifested arthritic signs. The elbow was affected in 7 cases, the knees in 4, and the wrists in 2. Polyarthritis was noted in 4 cases. The average time for the joint manifestations to appear was six days after the onset of the disease. The duration of actual symptoms was eight and a half days. The only treatment required to gain complete function and recovery was immobilization of the involved joint with splints and a flannel bandage. Passive motion and physiotherapy were instituted as soon as it was thought that active inflammation of the joint had subsided. The arthritis appeared to be periartritic, with thickening and inflammation about the joint but no active suppuration within the joint itself. This is in agreement with the observations of Herrick and Parkhurst.²¹

One case of purulent conjunctivitis, having Type 1 meningococci as the etiologic agent, was observed in a boy of eleven. Boric irrigations and sulfadiazine orally cleared the conjunctivitis, as well as the meningitis, without any complications.

A boy of nine developed complete aphasia one week after hospitalization. This gradually cleared without treatment, leaving no residual signs.

SUMMARY

A series of 72 cases of meningococcal infection in children is presented.

Most cases gave a story of acute onset, ushered in by nausea and vomiting, headache, stiff neck and a skin rash. This rash was a valuable aid in the diagnosis of meningococcemia.

Neurologic symptoms were present in all cases having meningeal involvement. Whereas children under three often had convulsions, older children rarely did.

The predominant type of organism was a Type 1 meningococcus, occurring in 76 per cent of the cases in which cultures were positive.

All cases were treated with sulfadiazine.

The most frequent complication was arthritis, occurring in 12 per cent of the cases. Complete recovery from the arthritis resulted in all cases.

A mortality of 8 per cent occurred, all but 1 of the 6 fatal cases being of the Waterhouse-Friderichsen type. Four children with this syndrome survived.

for three days before hospitalization and died shortly after admission.

LABORATORY FINDINGS

A lumbar puncture was performed on every patient. Ten cases (7 per cent) showed no organisms in the spinal fluid and were therefore classified as meningococcemia without meningitis; six of these patients were under four years of age. Sixty-two patients had a cloudy spinal fluid, with an average count of 6620 cells, 40 to 98 per cent of which were polymorphonuclear (leukocytes).

The sugar content was measured by the rapid method described by Alexander,¹⁷ which has proved extremely reliable and timesaving, being especially valuable at night when ordinary laboratory facilities are unavailable. Absence or diminution of sugar was found in all purulent spinal fluids.

Despite the presence of pus, in 13 cases (29 per cent), the fluid was sterile on culture. Of these cases, 5 exhibited intracellular and extracellular gram-negative diplococci on smear. In the 59 cases in which meningococci were recovered from the spinal fluid or blood, they proved to be Type 1 in 55 (76 per cent) and Type 2a in 4 (5 per cent).

The white-cell count on admission averaged 18,050, with a range of 8200 to 39,100. The blood cultures of 24 patients (33 per cent) failed to grow meningococci, although these organisms were isolated from the spinal-fluid culture or visualized on direct smear from the petechiae in most of these cases. The fact that bacteremia exists in the early stage of the disease and is transitory possibly accounts for the many negative blood cultures.¹⁸ No significant anemia directly attributable to the disease could be demonstrated.

TREATMENT

Prompt and adequate treatment in this disease is imperative and often lifesaving. The entire series of cases was treated with sulfadiazine, orally, subcutaneously or intravenously. In many cases all three methods were employed.

The following outline is a summary of the treatment used in all cases:

A lumbar puncture was done on all suspected cases. If purulent fluid was found, 10 to 20 cc. was removed to reduce the intracranial pressure. This procedure often transformed a disoriented, irritable child into a quiet, sleeping one. The spinal fluid was drained into three sterile tubes, — one for culture, one for a cell count and one for the determination of sugar, chloride and globulin.

Blood for culture and for a white-cell count was taken.

Sodium sulfadiazine was then given by slow intravenous drip in a dosage of 33 to 44 mg. ($\frac{1}{2}$ to $\frac{3}{4}$ gr.) per pound of body weight. In the

case of small children, where there is often technical difficulty in administering intravenous therapy, it was found that subcutaneous sodium sulfadiazine was useful. This drug when given in normal saline solution, diluted not to exceed 5 per cent concentration, produces blood levels of 10 to 12 mg. per 100 cc. in half an hour (Jorgensen and Greeley¹⁹).

Intravenous 5 per cent glucose in normal saline solution was then given to combat the almost universal acidosis and ketosis.

When the blood pressure was low and evidence of the Waterhouse-Friderichsen syndrome was present, 5 cc. of adrenocortical extract was given. This was put into a solution of 15 per cent glucose in normal saline solution and administered by slow intravenous infusion every four hours. The salt and glucose were given to restore the electrolyte imbalance and the depletion of glycogen stores. Synthetic desoxycorticosterone was also given in oily solution intramuscularly.

Sedation was used if the patient continued to be restless. The barbiturates, given either rectally or parenterally, proved to be satisfactory. Lumbar puncture and consequent relief of intracranial pressure, however, seemed to relax the patients enough so that little sedation was needed.

Six hours after the parenteral sulfadiazine had been given, oral sulfadiazine was administered and in most cases was retained without vomiting. This treatment was continued with 10 mg. (1/6 gr.) per pound of body weight every four hours.

If a patient showed evidence of recurrent intracranial pressure by convulsions, persistent vomiting, restlessness or irritability, a lumbar puncture was performed as often as once every four or six hours.

The following day a routine lumbar puncture was done and the spinal fluid was examined for cells, sugar and organisms. It was found that the sugar is the most reliable index of therapy, for if the spinal fluid has been sterilized, the sugar is almost always at a normal or near-normal level.

The urine was closely watched for evidence of sulfadiazine crystals or hematuria. Should these appear, fluids were forced immediately by mouth as well as intravenously, to promote diuresis. Sodium bicarbonate by mouth was also useful in promoting a more alkaline urine. If the urinary findings persisted, however, a shift to the more soluble sulfanilamide was made.

The average duration of chemotherapy was ten days. Sulfadiazine blood levels were determined on alternate days while the drug was being administered. A level of 10 to 12 mg. per 100 cc. was considered adequate.

Following the above treatment, a striking fall in temperature was usually noted. Forty-five pa-

patients were afebrile one week after treatment, and 36 reached a normal temperature and a general feeling of improvement in four days (Fig. 3).

COMPLICATIONS

Arthritis was the most frequent complication encountered, 9 cases (12 per cent) showing evidence of it. This is a somewhat higher incidence than was

FIGURE 3. Mortality.

reported in Boulduan's series cited by Schein.²⁰ In which 13 of 169 patients (7.7 per cent) manifested joint signs. The elbow was affected in 7 cases, knees in 4, and the wrists in 2. Polyarthritis was noted in 4 cases. The average time for the joint manifestations to appear was six days after the onset of the disease. The duration of actual symptoms was eight and a half days. The only treatment required to gain complete function and recovery was immobilization of the involved joint with casts and a flannel bandage. Passive motion and physiotherapy were instituted as soon as it was thought that active inflammation of the joint had subsided. The arthritis appeared to be periartritic, with thickening and inflammation about the joint but no active suppuration within the joint itself. This is in agreement with the observations of Merrick and Parkhurst.²¹ One case of purulent conjunctivitis, having Type I meningococci as the etiologic agent, was observed in a boy of eleven. Boric irrigations and sulfadiazine orally cleared the conjunctivitis, as well as the meningitis, without any complications. A boy of nine developed complete aphasia one week after hospitalization. This gradually cleared without treatment, leaving no residual signs.

SUMMARY

A series of 72 cases of meningococcal infection in children is presented.

Most cases gave a story of acute onset, ushered in by nausea and vomiting, headache, stiff neck and a skin rash. This rash was a valuable aid in the diagnosis of meningococcemia.

Neurologic symptoms were present in all cases having meningeal involvement. Whereas children under three often had convulsions, older children rarely did.

The predominant type of organism was a Type I meningococcus, occurring in 76 per cent of the cases in which cultures were positive.

All cases were treated with sulfadiazine.

The most frequent complication was arthritis, occurring in 12 per cent of the cases. Complete recovery from the arthritis resulted in all cases.

A mortality of 8 per cent occurred, all but 1 of the 6 fatal cases being of the Waterhouse-Friderichsen type. Four children with this syndrome survived.

SURGICAL MEASURES IN DYSMENORRHEA*

LOUIS E. PHANEUF, M.D., Sc.D.†

BOSTON

DYSMENORRHEA, or painful menstruation, is a symptom and not a primary disease. It is referred to as primary when no gross anatomic lesions can be found to account for it, and as secondary when organic disease of the pelvic organs or organs adjacent to them is responsible for the pain. In either case, when the symptom is mild to moderate, relief may be obtained by means of rest, the application of heat to the lower abdomen and the

metrium that is responsible for the improvement. The use of the intrauterine stem or pessary, which carried considerable vogue a quarter of a century ago, has fortunately been almost entirely abandoned. This instrument, which was sutured to the cervix and left in the uterus for a period of one to three months, did relieve the pain of menstruation in a number of cases, but, as might be expected, it was not infrequently followed by serious pelvic

FIGURE 1. Composite Drawing Showing the Numerous Lesions That Cause Dysmenorrhea and the Various Surgical Measures That Are Employed in Their Treatment.

administration of analgesic drugs. Some of the newer antispasmodic drugs, by relaxing the uterine muscle, have proved of benefit, and in a certain group, hormones, notably progesterone, have been of value.

In severe cases and in those in which conservative therapy has failed, it frequently becomes necessary to resort to surgical measures. In primary dysmenorrhea thorough dilatation of the cervix, under anesthesia, usually brings relief, sometimes for a number of months and sometimes permanently. This is probably the oldest procedure in use, and years ago it was followed by curettage. Since then, however, it has been determined that it is the dilatation of the cervix rather than the removal of the endo-

metrium that is responsible for the improvement. The plastic operations of Dudley and Pozzi, designed to enlarge the external os of the cervix, were based on the theory that the cause of dysmenorrhea is mechanical. An annoying leukorrhea often followed this procedure however, and in many cases gynecologists have had to reconstruct the cervix to as near its original condition as possible in order to overcome this abnormal secretion.

It is in primary dysmenorrhea that presacral neurectomy or resection of the superior hypogastric plexus finds its greatest field of usefulness. The results are frequently dramatic, since it is not uncommon for young women who have been crippled each month by dysmenorrhea to menstruate without discomfort after this therapeutics. Because of the striking results there is the danger of being led

*Presented at the one hundred and sixty-third meeting of the Massachusetts Medical Society, Section of Obstetrics and Gynecology, May 24, 1944.

†Professor of gynecology, Tufts College Medical School, surgeon-in-chief, Department of Obstetrics and Gynecology, Carney Hospital; director, American Board of Obstetrics and Gynecology.

by one's enthusiasm to perform this operation on those who might be relieved by conservative measures. It should be resorted to only in those cases in which all other methods have failed, and should be reserved for the so-called "spastic" or uterine form of dysmenorrhea, a condition in which the patient experiences severe cramps. It has but little value in dysmenorrhea of ovarian origin.

Secondary dysmenorrhea is pain at the time of menstruation when certain pathologic lesions exist in the generative and adjacent organs. By the surgical ablation of the pathologic process concerned, menstruation may become nearly or entirely painless. Thus, in the presence of myomas that cause pain by the distortion of the uterus and by irregular contractions, in an attempt to expel blood clots, myomectomy or the enucleation of the tumors may result in marked improvement. The excision of endometrial polyps may give similar results, and ablation of the ovaries for ovarian cysts may be responsible for the cessation of menstrual pain.

It is a recognized fact that acquired dysmenorrhea is almost always due to endometriosis of the external variety, in which condition the ovaries are involved in the process. Relief of menstrual pain may be obtained by the resection or ablation of the ovaries, depending on the extent of the disease. Salpingophorectomy, unilateral or bilateral, may have to be resorted to for endometriosis and for chronic pelvic inflammatory disease in the form of adhesions, hydrosalpinx or chronic pyosalpinx. The last intervention may be performed independently or in association with hysterectomy. In such disorders as uterine myomas and adenomyosis, — also known as internal endometriosis, — hysterectomy, fundic, subtotal or total, with or without the ablation of the adnexa, may have to be employed. In corpus carcinoma the total removal of the uterus and its adnexa is the operation of choice. Since the manage-

ment of the above-named lesions, which are accompanied by painful menstruation, requires the removal of the uterus or ovaries, or both, thus bringing about the cessation of menstruation, it is obvious that the patient will be relieved of dysmenorrhea.

A number of years ago dysmenorrhea was attributed, in a large measure, to the retroposed uterus and was treated by dilatation and curettage and suspension of the uterus. Uterine suspension nowadays is not so frequently performed as it was in the past. When, however, a retroposition is discovered during a presacral neurectomy, the abdomen being open and the pelvic organs being accessible, the position of the uterus is usually corrected at the same time. The pain occasioned by mechanical disturbances of the vermiform appendix, as found in the retrocecal appendix and the distorted appendix due to adhesions, may be increased at the time of the catamenia. Lysis of the adhesions and an appendectomy frequently help the condition. Similar results may be obtained by attending to the lesions of the ureters, which appear as strictures, calculi and hydroureter. Diseases of the sigmoid and rectum, whether neoplastic, inflammatory or due to endometriosis, which may also cause increased pain at menstruation, demand proper surgical attention, and this secondarily effects improvement in or a cure of the dysmenorrhea. In membranous dysmenorrhea, in which a cast of the endometrium is thrown off with each menstruation, beneficial results have been obtained by curettage and a small dose of radium, about 200 to 250 mg. hr.

SUMMARY

The operative procedures in primary and secondary dysmenorrhea are discussed, and the operative procedures of the contiguous organs, the diseases of which are responsible for pain at the time of menstruation, are considered.

270 Commonwealth Avenue

SURGICAL MEASURES IN DYSMENORRHEA*

LOUIS E. PHANEUF, M.D., Sc.D.†

BOSTON

DYSMENORRHEA, or painful menstruation, is a symptom and not a primary disease. It is referred to as primary when no gross anatomic lesions can be found to account for it, and as secondary when organic disease of the pelvic organs or organs adjacent to them is responsible for the pain. In either case, when the symptom is mild to moderate, relief may be obtained by means of rest, the application of heat to the lower abdomen and the

metrium that is responsible for the improvement. The use of the intrauterine stem or pessary, carried considerable vogue a quarter of a century ago, has fortunately been almost entirely abandoned. This instrument, which was sutured to the cervix and left in the uterus for a period of three months, did relieve the pain of menstruation in a number of cases, but, as might be expected, was not infrequently followed by serious

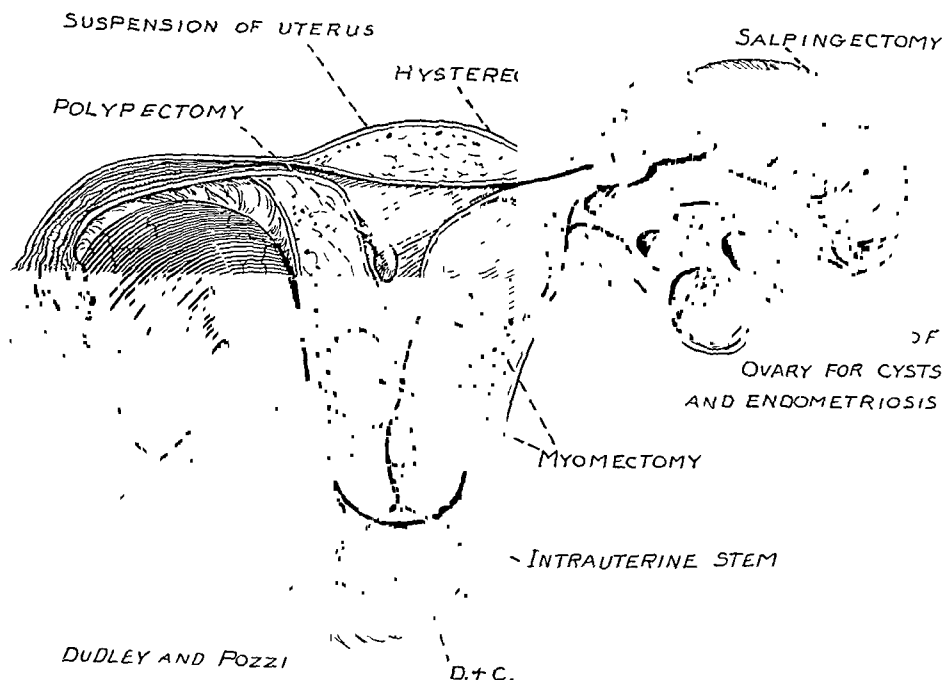

FIGURE 1. Composite Drawing Showing the Numerous Lesions That Cause Dysmenorrhea and the Various Surgical Measures That Are Employed in Their Treatment.

administration of analgesic drugs. Some of the newer antispasmodic drugs, by relaxing the uterine muscle, have proved of benefit, and in a certain group, hormones, notably progesterone, have been of value.

In severe cases and in those in which conservative therapy has failed, it frequently becomes necessary to resort to surgical measures. In primary dysmenorrhea thorough dilatation of the cervix, under anesthesia, usually brings relief, sometimes for a number of months and sometimes permanently. This is probably the oldest procedure in use, and years ago it was followed by curettage. Since then, however, it has been determined that it is the dilatation of the cervix rather than the removal of the endo-

metrium, which rarely resulted in death but which caused sterility in a number of the women.

The plastic operations of Dudley and Pozzi, designed to enlarge the external os of the cervix, are based on the theory that the cause of dysmenorrhea is mechanical. An annoying leukorrhea often followed this procedure however, and in many cases gynecologists have had to reconstruct the cervix as near its original condition as possible in order to overcome this abnormal secretion.

It is in primary dysmenorrhea that presacral neurectomy or resection of the superior hypogastric plexus finds its greatest field of usefulness. The results are frequently dramatic, since it is not uncommon for young women who have been crippled each month by dysmenorrhea to menstruate without discomfort after this therapy. Because of the striking results there is the danger of being led

*Presented at the one hundred and sixty-third meeting of the Massachusetts Medical Society, Section of Obstetrics and Gynecology, May 24, 1944.

this study. The distribution of these cases is shown in Table 1.

Merritt and Fremont-Smith¹ included 30 cases of metastatic brain tumor. The cerebrospinal fluid was 44 mg. per 100 cc. or less in 10 cases, 45 to 99 mg. in 15 cases, 100 to 199 mg. in 5 cases, and 200 mg. or more in 2 cases. Hare² determined the spinal-fluid protein in 6 cases of metastatic neoplasm. In 2 cases it was normal; in the other 4 it was 66, 77, 125 and 200 mg. per 100 cc., respectively. In Ayer's³ series, only one metastatic tumor was included, and in this case the protein of the lumbar cerebrospinal fluid was elevated.

The differential diagnosis of glioblastoma multiforme and metastatic neoplasms, which is often confusing owing to the fact that both these tumors develop signs and symptoms rather rapidly, is not helped by determining the spinal-fluid protein. In this series it was normal (40 mg. per 100 cc. or less) in only 19 and 9 per cent, respectively, and the comparative percentages for fluids with varying amounts of increased protein are very close, as shown in Table 1.

Table 2 indicates the separate findings in the 43 cases of metastatic tumor.

It is interesting to note that in 13 of the 26 cases in which the site of the primary lesion was found, it originated from the lungs. This certainly gives support to the rule that all brain tumor suspects should have chest x-ray examination as a routine procedure.

The fact that a neoplasm may be on the surface and even invade the ependyma of the ventricles without causing an elevation of the cerebrospinal-fluid protein is shown in Cases 2, 3 and 4. In all the cases with the greatest elevation of protein, however, the lesions were superficially located in

the cerebral hemispheres. Subcortical lesions are also capable of producing a marked elevation of protein, as shown in Cases 31, 33, 34 and 36. In the metastatic tumors, there was no apparent correlation between the type of primary tumor and the degree of elevation of protein.

The tendency of metastatic lesions to invade the supratentorial areas is brought out in this study, since there were only 6 patients with subtentorial metastatic neoplasms. Also, the protein was not markedly elevated in any of these, the highest level being 52 mg. per 100 cc. Hare² has found that primary subtentorial tumors, exclusive of acoustic neuromas, do not cause so great an increase in cerebrospinal fluid protein as do the supratentorial lesions. This is also apparently true of metastatic tumors.

SUMMARY

The average protein content of lumbar cerebrospinal fluid in 43 cases of metastatic brain tumors was 99 mg. per 100 cc.

Ninety-one per cent of the cases had a protein content greater than 40 mg.

The highest protein content was found in the cases with superficial cerebral metastases.

The patients with supratentorial metastases had a higher protein content than did those with subtentorial lesions.

The protein content of lumbar cerebrospinal fluid alone does not differentiate a metastatic neoplasm from a primary brain tumor.

an aid in differentiating these two conditions. All the 43 cases of metastatic brain tumor in this series

*Formerly, resident in neurosurgery, Massachusetts General Hospital, Boston

†Fellow in surgery, Cleveland Clinic, Cleveland.

fluid protein of an unselected series of verified primary brain tumors, including astrocytoma, glioblastoma multiforme, meningioma, medulloblastoma and acoustic neuroma, was carried in

this study. The distribution of these cases is shown in Table 1.

Merritt and Fremont-Smith¹ included 30 cases of metastatic brain tumor. The cerebrospinal fluid was 44 mg. per 100 cc. or less in 10 cases, 45 to 99 mg. in 15 cases, 100 to 199 mg. in 5 cases, and 200 mg. or more in 2 cases. Hare² determined the spinal-fluid protein in 6 cases of metastatic neoplasm. In 2 cases it was normal; in the other 4 it was 66, 77, 125 and 200 mg. per 100 cc., respectively. In Ayer's³ series, only one metastatic tumor was included, and in this case the protein of the lumbar cerebrospinal fluid was elevated.

The differential diagnosis of glioblastoma multiforme and metastatic neoplasms, which is often confusing owing to the fact that both these tumors develop signs and symptoms rather rapidly, is not helped by determining the spinal-fluid protein. In this series it was normal (40 mg. per 100 cc. or less) in only 19 and 9 per cent, respectively, and the comparative percentages for fluids with varying amounts of increased protein are very close, as shown in Table 1.

Table 2 indicates the separate findings in the 43 cases of metastatic tumor.

It is interesting to note that in 13 of the 26 cases in which the site of the primary lesion was found, it originated from the lungs. This certainly gives support to the rule that all brain tumor suspects should have chest x-ray examination as a routine procedure.

The fact that a neoplasm may be on the surface and even invade the ependyma of the ventricles without causing an elevation of the cerebrospinal-fluid protein is shown in Cases 2, 3 and 4. In all the cases with the greatest elevation of protein, however, the lesions were superficially located in

the cerebral hemispheres. Subcortical lesions are also capable of producing a marked elevation of protein, as shown in Cases 31, 33, 34 and 36. In the metastatic tumors, there was no apparent correlation between the type of primary tumor and the degree of elevation of protein.

The tendency of metastatic lesions to invade the supratentorial areas is brought out in this study, since there were only 6 patients with subtentorial metastatic neoplasms. Also, the protein was not markedly elevated in any of these, the highest level being 52 mg. per 100 cc. Hare² has found that primary subtentorial tumors, exclusive of acoustic neuromas, do not cause so great an increase in cerebrospinal fluid protein as do the supratentorial lesions. This is also apparently true of metastatic tumors.

SUMMARY

The average protein content of lumbar cerebrospinal fluid in 43 cases of metastatic brain tumors was 99 mg. per 100 cc.

Ninety-one per cent of the cases had a protein content greater than 40 mg.

The highest protein content was found in the cases with superficial cerebral metastases.

The patients with supratentorial metastases had a higher protein content than did those with subtentorial lesions.

The protein content of lumbar cerebrospinal fluid alone does not differentiate a metastatic neoplasm from a primary brain tumor.

MEDICAL PROGRESS

TUBERCULOSIS

JOSEPH D. WASSERSUG, M.D.*

SOUTH BRAINTREE, MASSACHUSETTS

TUBERCULOSIS is a disease of innumerable ramifications; its many branches reach out from medicine and the allied sciences into the distant realms of sociology and law. Significant as all these ordinarily are, in time of war the main interest is in its great military importance.

TUBERCULOSIS, WAR AND POSTWAR

Tuberculous Rejectees

Last year special emphasis was placed on the ways and means that had been designed to keep tuberculosis out of the armed services.¹ Now, after three years of war, attention is shifting from case finding in inductees to the proper handling of tuberculous rejectees and veterans.

Although the follow-up of men rejected for tuberculosis varies in some details throughout the country, the general principles followed are fundamentally alike everywhere. Registrants disqualified for military service because of tuberculosis become, to a great extent, the responsibility of public-health officials, and their cases are submitted for study and review by competent authorities. Such follow-up is necessary since the degree of activity of a chest lesion cannot be determined from a single x-ray film. In fact, a definite diagnosis of tuberculosis cannot be made from a single roentgenogram. Hence, follow-up enables one to sort out the tuberculous from the nontuberculous, and the active from the inactive or arrested. The programs adopted by Chicago^{2, 3} Wayne County, Michigan,⁴ and Massachusetts⁵ have recently been discussed.

In Chicago, the Medical Advisory Board in conjunction with the Municipal Tuberculosis Sanitarium determines the disposition of cases rejected for tuberculosis. Of 1907 men with pulmonary tuberculosis seen in Chicago, 1279 were finally classified as 4F and 628 as 1A. Of the total number, 1431 cases (75.4 per cent) had never been previously reported to the Board of Health—a striking demonstration of the value of this type of case finding. On further study by the Collapse Therapy Clinic, 429 were selected as prospective candidates for treatment, and of these, 59 are now receiving pneumothorax.

In Massachusetts, rejectees for pulmonary diseases are first reported to the State Department of Public Health, and are subsequently referred to local

boards of health for further clinical and laboratory study. Practically all the rejectees are eventually examined in clinics conducted by the city, county or state. Of 2270 men so studied, 1795 (79.0 per cent) were rejected for pulmonary tuberculosis, 1672 of them with the reinfection type of disease. Complete follow-up was obtained in 1125 cases, and the diagnosis of reinfection-type disease was confirmed in every case. Of 395 men rejected as "pulmonary suspects," 160 received further study, and of these 86 were found to have tuberculosis. Important, though less striking than the Chicago demonstration, was the fact that two thirds of the cases of pulmonary tuberculosis that were discovered had never been reported to boards of health. Besides, 60 per cent of the cases were believed to be in need of immediate hospitalization. Thus, follow-up returns some men to the Army and sends others to sanatoriums or clinics for therapy.

Tuberculous Veterans

In spite of the many safeguards that have been set up to keep tuberculosis out of the armed services, it is disconcerting to learn that, up to the present, discharges from the Army because of this disease number approximately 10,000.⁶ Freer⁷ has estimated that 35 of every 10,000 men accepted for service have minimal, scarred or arrested lesions, and attributes some of the mistakes that have been made to inexperience, haste and fatigue of the examiners.

Myers,⁸ in a critical review, further analyzes the reasons for the failure to detect all cases of tuberculosis on induction into military service. Listed among the salient points are omission of x-ray examination of about 1,000,000 men who were first inducted, the use of the 4-by-5 inch or 35-mm. film instead of the 14-by-17-inch film, and the fact that even the best films cannot detect every case of tuberculosis. Myers stresses the role that could have been played by tuberculin testing of inductees and laments its exclusion from routine induction examinations. His original paper deserves careful reading.

There is, nevertheless, some reason to believe that the number of discharges for tuberculosis will soon show a progressive decline, and the figures from the Navy⁹ and from the Army Air Center at Nashville¹⁰ lend encouragement to this viewpoint. Men examined for air-crew training at this center are between eighteen and twenty-six years of age,

*Assistant physician, Norfolk County Hospital

and all have been in the Army for varying periods up to two and a half years. Examination of this group by the photoroentgen method revealed that the percentage incidence of tuberculosis in the first 32,000 was 0.207 per cent, in the second 32,000 0.169 per cent, and in the third only 0.120 per cent. In the last 10,000 examinations, indeed, it was less than 0.050 per cent. It is of some interest, too, that of the active cases of tuberculosis discovered, 112 were in the minimal stage, 10 were moderately advanced, and only 2 were advanced.

The Veterans' Administration is making every effort to absorb the load of new cases of tuberculous victims who have been discharged from military service. Statistics computed as of January 31, 1944, disclose that a total of 6114 beds were available for tuberculous veterans.¹¹ Under the so-called "G. I. Bill of Rights," plans were developed to provide an additional 3500 beds,¹² and this project has already received presidential approval.¹³

Unfortunately, tuberculosis among veterans is but little controlled by the availability of hospital beds or the expenditure of huge sums of money. Dublin¹⁴ points out that financial arrangements to veterans are such as to have had "the unfortunate effect of providing an incentive to many men to discontinue hospital treatment and to attempt a cure at home." In spite of the many millions of dollars that are being spent, the experience of veterans' hospitals has been unfavorable. For example, in 1942 less than 2 per cent of the patients were discharged as arrested. Hospitalization was considered incomplete in more than half the cases.

The reason for this alleged "deplorable situation," according to Dublin,¹⁴ is that veterans come and go as they please. Some have had as many as twenty-four different admissions; six to eight admissions is a commonplace occurrence. Yet the consequences of this indifference to treatment are far reaching. "The discharge of men," says this author, "before they are cured has left its toll on the entire country." Obviously, laws pertaining to veterans' benefits must be modified if tuberculosis among them is to be controlled.

The attitude of World War II veterans toward tuberculosis can arouse nothing but pessimism. Wolford¹⁵ reports that of 2275 such veterans treated for active pulmonary tuberculosis, approximately 31 per cent had left against medical advice before treatment was completed. Dublin¹⁴ writes, "There is already evidence that all is not well with the new tuberculosis victims, and that they are showing the same restlessness, the same abandonment of hospital care." An understanding of the dangers and seriousness of tuberculosis appears to be sadly lacking in too many servicemen. Altogether too often the term "tuberculosis" is regarded as being synonymous with a "short, pleasant vacation in the mountains."

United States Public Health Service

The establishment of a Division of Tuberculosis Control in the United States Public Health Service on July 6, 1944, may be "one of the most important steps yet taken toward the ultimate control of this disease."¹⁶ For this reason Section 2 of the bill¹⁷ under which this division was founded is quoted in detail.

Section 2. To enable the Surgeon General of the Public Health Service (1) to make studies, investigations, and demonstrations with respect to developing more effective measures of prevention, treatment and control of tuberculosis; (2) to assist through state health authorities, by grants as otherwise provided in this act, states, counties, health districts, and other political subdivisions of states in establishing and maintaining adequate measures for the prevention, treatment, and control of tuberculosis, including construction, maintenance, and operation, and the training of personnel for state and local health work; (3) to control the spread of tuberculosis in interstate traffic; and (4) to meet the cost of pay allowances, and traveling expenses of commissioned officers and other personnel of the Public Health Service detailed to assist in carrying out the purposes of this act, and for administration of this act, there is hereby authorized to be appropriated for the fiscal year ending June 30, 1945, a sum of \$10,000,000 and for each fiscal year thereafter a sum sufficient to carry out the purposes of this act.

In several articles, Hilleboe^{16, 18, 19} has elaborated on the purposes of the Division of Tuberculosis and has reviewed some of its accomplishments. The objectives of an adequate control program, he insists, must include mass x-ray examination (eventually, of the entire population), follow-up of discovered cases, isolation of open cases, treatment for active cases, periodic check-up, health education, research and financial aid to the afflicted. For the first step — mass roentgenography — the Public Health Service has available ten transportable units, some of which are equipped with the new photoelectric timer — a device that simplifies x-ray procedure by eliminating the necessity for measuring each subject's chest.

Industrial areas and large cities are the chief targets of the United States Public Health Service at the present time. Of 778,496 war workers examined by photofluorography up to May 31, 1944, approximately 1.0 per cent were found to have tuberculosis, and in two thirds of these cases the disease was in the minimal stage. Hiebert²⁰ reports a survey of 21,427 persons conducted in Kansas with a unit borrowed from the United States Public Health Service. Attention was centered on persons in war industries and "critical areas," and definite reinfection tuberculosis was found in 0.5 per cent. These figures are comparable to those of Massachusetts, where an x-ray survey of 28,190 persons in thirty-nine industrial companies revealed 352 cases of pulmonary tuberculosis, 114 of which were probably active.²¹

Hospital Personnel

It is common knowledge that medical students, nurses and others who assist in the care of tuberculous patients are exposed to a definite risk of

MEDICAL PROGRESS

TUBERCULOSIS

JOSEPH D. WASSERSUG, M.D.*

SOUTH BRAINTREE, MASSACHUSETTS

TUBERCULOSIS is a disease of innumerable ramifications; its many branches reach out from medicine and the allied sciences into the distant realms of sociology and law. Significant as all these ordinarily are, in time of war the main interest is in its great military importance.

TUBERCULOSIS, WAR AND POSTWAR

Tuberculous Rejectees

Last year special emphasis was placed on the ways and means that had been designed to keep tuberculosis out of the armed services.¹ Now, after three years of war, attention is shifting from case finding in inductees to the proper handling of tuberculous rejectees and veterans.

Although the follow-up of men rejected for tuberculosis varies in some details throughout the country, the general principles followed are fundamentally alike everywhere. Registrants disqualified for military service because of tuberculosis become, to a great extent, the responsibility of public-health officials, and their cases are submitted for study and review by competent authorities. Such follow-up is necessary since the degree of activity of a chest lesion cannot be determined from a single x-ray film. In fact, a definite diagnosis of tuberculosis cannot be made from a single roentgenogram. Hence, follow-up enables one to sort out the tuberculous from the nontuberculous, and the active from the inactive or arrested. The programs adopted by Chicago^{2,3} Wayne County, Michigan,⁴ and Massachusetts⁵ have recently been discussed.

In Chicago, the Medical Advisory Board in conjunction with the Municipal Tuberculosis Sanitarium determines the disposition of cases rejected for tuberculosis. Of 1907 men with pulmonary tuberculosis seen in Chicago, 1279 were finally classified as 4F and 628 as 1A. Of the total number, 1431 cases (75.4 per cent) had never been previously reported to the Board of Health—a striking demonstration of the value of this type of case finding. On further study by the Collapse Therapy Clinic, 429 were selected as prospective candidates for treatment, and of these, 59 are now receiving pneumothorax.

In Massachusetts, rejectees for pulmonary diseases are first reported to the State Department of Public Health, and are subsequently referred to local

boards of health for further clinical and laboratory study. Practically all the rejectees are eventually examined in clinics conducted by the city, county or state. Of 2270 men so studied, 1795 (79.0 per cent) were rejected for pulmonary tuberculosis, 1672 of them with the reinfection type of disease. Complete follow-up was obtained in 1125 cases, and the diagnosis of reinfection-type disease was confirmed in every case. Of 395 men rejected as "pulmonary suspects," 160 received further study, and of these 86 were found to have tuberculosis. Important, though less striking than the Chicago demonstration, was the fact that two thirds of the cases of pulmonary tuberculosis that were discovered had never been reported to boards of health. Besides, 60 per cent of the cases were believed to be in need of immediate hospitalization. Thus, follow-up returns some men to the Army and sends others to sanatoriums or clinics for therapy.

Tuberculous Veterans

In spite of the many safeguards that have been set up to keep tuberculosis out of the armed services, it is disconcerting to learn that, up to the present, discharges from the Army because of this disease number approximately 10,000.⁶ Freer⁷ has estimated that 35 of every 10,000 men accepted for service have minimal, scarred or arrested lesions, and attributes some of the mistakes that have been made to inexperience, haste and fatigue of the examiners.

Myers,⁸ in a critical review, further analyzes the reasons for the failure to detect all cases of tuberculosis on induction into military service. Listed among the salient points are omission of x-ray examination of about 1,000,000 men who were first inducted, the use of the 4-by-5 inch or 35-mm. film instead of the 14-by-17-inch film, and the fact that even the best films cannot detect every case of tuberculosis. Myers stresses the role that could have been played by tuberculin testing of inductees and laments its exclusion from routine induction examinations. His original paper deserves careful reading.

There is, nevertheless, some reason to believe that the number of discharges for tuberculosis will soon show a progressive decline, and the figures from the Navy⁹ and from the Army Air Center at Nashville¹⁰ lend encouragement to this viewpoint. Men examined for air-crew training at this center are between eighteen and twenty-six years of age.

*Assistant physician, Norfolk County Hospital

dramatic cure for tuberculosis. Often by innuendo, less frequently by misstatement, preliminary in vitro or guinea-pig experiments have been presented as clinical successes. Usually these alleged "cures" depend on the discovery of a new "wonder" chemical or so-called "protective" vaccine. Chemicals and vaccines are being developed, but progress in this direction is slower and less certain than the laity is led to believe.

The chemical compounds of greatest promise are the sulfones. The parent drug, 4,4'-diaminodiphenylsulfone, is a potent agent for combating tuberculosis in guinea pigs,³⁶ but its toxicity limits its clinical application. Derivatives are therefore being synthesized in an attempt to obtain more suitable compounds for therapeutic use. The two derivatives that have received the greatest amount of study are promin (sodium *p,p'*-diaminodiphenylsulfone-*N*, *N'*-didextrose sulfonate) and diasone (disodium formaldehyde sulfoxylate, 4,4'-diaminodiphenylsulfone).

Three reports emphasize the value of promin in experimental tuberculosis in guinea pigs. In one group of tests, a favorable therapeutic effect in these animals was noted even though treatment was delayed for six weeks and the promin was given only in alternate weeks.³⁷ In another series of experiments, the average survival time of the treated animals was twice as long as that of untreated guinea pigs.³⁸ If the guinea pigs were first vaccinated, the subsequent administration of promin caused an even greater inhibition in the progress of the disease than occurred in the nonvaccinated animals.³⁹

Clinically, promin is not considered to be a particularly potent curative agent against human tuberculosis.⁴⁰ At the Wisconsin State Sanatorium, 27 patients with poor prognosis were given from 0.4 to 1.2 gm. of promin daily by mouth for a nineteen-month period. The status of 16 patients was ultimately evaluated; the improvement noted was greater than would otherwise have been expected. In another group of 36 adequately treated patients, marked improvement was observed in 7 and moderate improvement in 5.⁴¹ The authors of this report conclude, "Prolonged administration of promin orally is clinically feasible . . . [and makes] more extensive and more exactly controlled observations highly desirable." They stress the point that human beings, unlike guinea pigs, have a high degree of natural resistance to tuberculosis and are usually in need of but little aid in order to turn a losing fight against this disease into victory. When the fight is against tuberculous meningitis, however, promin has proved to be without any beneficial result in either prolonging or maintaining life or altering the course of the disease.⁴²

The clinical use of diasone has been discussed in some detail by Petter,⁴³⁻⁴⁵ who fed the compound to 100 volunteers and analyzed the results of treat-

ment in 44 of them. Diasone, it was concluded, is not an ideal chemotherapeutic agent but is to be regarded as a useful adjunct to other treatments. No correlation was discovered between the blood level of diasone and the clinical course. Toxic reactions were not infrequent but were not marked or irreversible. On the other hand, one very severe dermatitis was reported in another series of 63 cases.⁴⁶ Jellinek⁴⁷ found no useful effect from diasone in 15 cases of extrapulmonary tuberculosis.

A significant addition to the growing list of chemotherapeutic agents is promizole (4,2'-diaminodiphenyl-5'-thiazolesulfone).^{48, 49} It is apparently the least toxic of the therapeutic chemicals and is comparable in its effectiveness for guinea pigs to promin and diasone. Experimentally it is administered in daily doses of 200 to 250 mg., and favorable effects can be noted even in guinea pigs that have been inoculated ten to fourteen weeks earlier. Because of its low toxicity, it has been given orally to 56 patients in daily doses of 10 to 16 gm., but insufficient time has elapsed for evaluation of the results. A two-year-old child who presumably had tuberculous meningitis was treated with promizole and recovered,⁵⁰ but the diagnosis was not established with bacteriologic certainty and the result of a tuberculin test was not reported.

Among other compounds that have been tested for their bacteriostatic or bactericidal action on tubercle bacilli are certain naphthoquinones⁵¹ and stilbestrol.⁵² The latter exhibits a surprisingly strong bactericidal action in vitro. Penicillin and penicillium extracts have, by and large, no effect,⁵³ but another mold, as yet unidentified, is reported as having a bacteriostatic action.⁵⁴

Practically all the workers in this field of chemotherapy recognize the difficulties that are encountered in evaluating any agent for therapeutic use in human beings. The need for large numbers of cases, carefully matched controls, bacteriologic proof of disease and the objective, impartial evaluation of its course is stressed by Hinshaw and Feldman.⁵⁵ Pinner,⁵⁶ on the other hand, believes that absolute-control experiments in human beings are an impossible attainment and that any therapeutic agent, to be satisfactory, must be decisive in its results or is doomed to eventual discard.

SURGERY

Lloyd^{57, 58} has initiated a one-man campaign that is destined eventually to put pneumonology on a broader, sounder basis. Two features of this campaign are especially noteworthy. The first — inclusion of a chest service in a greater number of general hospitals — is designed to bring treatment for tuberculosis closer to the many persons who cannot obtain this service conveniently at present. The second feature — a bronchoscope for every lung specialist — is a natural outgrowth of the increased

infection. Schultz²² cites the cases of 24 medical students, 8 of whom developed active disease. He presents evidence that this group was carelessly exposed, and goes on to suggest that medical school faculties include in their curriculums definite programs to teach students the technic of handling patients with infectious diseases and that facilities for such precautions be provided. Certainly it is as important for students to learn how to protect themselves against tuberculosis as it is to detect it.

A recent survey by the Royal College of Physicians²³ is also instructive for the hints it provides for controlling tuberculosis among nurses. Mantoux tests and x-ray examinations were performed on 3764 nurses shortly after their entry into training school. Study of tuberculosis morbidity in those whose x-ray films were clear on entry revealed that 33 cases had occurred in 452 nurses initially Mantoux negative, but only 43 cases in 2120 initially positive. The annual case rate was 7.4 per 1000 for Mantoux-positive nurses, in contrast to 18.8 per 1000 for Mantoux-negative ones. It is therefore apparent that the young nurse who is tuberculin negative must be given special care and that her exposure to tuberculosis should be kept at a minimum.

Childress²⁴ reviews his experience with 5039 employees at the Grasslands Hospital, a general hospital of 800 beds, 300 of which are for tuberculous patients. If these employees are divided into two approximately equal groups, exposed and unexposed, it is found that 39 (1.8 per cent) of the exposed and 6 (0.2 per cent) of the unexposed developed tuberculosis. All these 45 employees originally had negative x-ray films and were symptom free. In this study, the laboratory was found to be a serious source of danger, since 5 active cases were discovered in the laboratory, in addition to several cases in physicians who worked there. There is no doubt that in many instances protection to laboratory workers against tuberculosis is wholly inadequate.

Foreign Countries

Throughout the world intensified programs for the control of tuberculosis are already under way or plans for the future are being laid. Mass photofluorographic check-up in Saskatchewan, Canada, has proved to be such a practical success that it has been stated that no city or municipality is so small or so large that it cannot raise the cost of such a survey.²⁵ In Alaska, where less than 100 beds are available for 2500 tuberculosis cases, proposals are being considered for the construction of hospitals to provide at least 400 more beds.²⁶ In Rio de Janeiro,²⁷ where tuberculosis is the leading cause of death, with an estimated death rate for 1944 of 309 per 100,000 population, and in other South American countries,²⁸ mobile x-ray units are being used and hospital facilities are being extended.

Reports from Victoria, Australia, indicate an increasing death rate from tuberculosis, and a program has now been launched that includes provision for 2000 beds and roentgenologic examination of every child at the age of twelve.²⁹ In fact, postwar plans have been made for compulsory chest x-ray examination of every person.³⁰

Trends and Perspectives

The tuberculosis mortality in the United States for the years 1939-1941 has been statistically analyzed by Yerushalmy and his co-workers.³¹ The death rate continues to show a gratifying decline; in 1942 it was 43.1 per 100,000 population, whereas in 1943 it was only 41.9. In highly industrial areas, however, especially in the north-central and north-eastern states, an increase has been noted.³²

A series of articles has appeared on the important problem of the apparently adequately treated patient whose sputum is occasionally positive or contains rare bacilli. Stokes³³ points out, "It cannot be denied that many patients with only a few bacilli in the sputum can and do lead comfortable, useful and economically productive lives and do not infect other members of their households." He recommends that discharge of patients from sanatoriums be not solely determined by the status of the sputum, but that consideration be given to such factors as age, sex, resistance, economic status and occupation.

In a more recent review, the Pottengers³⁴ call attention to the fact that tubercle bacilli may be detected on rare occasions in so-called "converted cases" if tests are done often enough and an exacting technic of examination is used. They believe that not every patient with an infection of the lung with rare bacilli in his sputum is necessarily suffering from active disease. In their studies, there has not been a single case in which a contact exposed to these patients has developed progressive clinical tuberculosis. Before discharge, a patient must indicate from every aspect that his lesion is healed; the sputum is but one item in the over-all picture.

Willis,³⁵ in a general discussion, has wisely summed up the problem as follows: "It is the duty of the laboratory to find tubercle bacilli wherever it can and to report them when found; the duty of the clinician is to evaluate the situation." The presence of tubercle bacilli may establish the diagnosis, but its significance may be totally different where therapy, discharge, prognosis and epidemiological connotations are concerned. Willis believes that there is a growing attitude of reasonableness about discharging patients for whom all has been done that can be done and who still occasionally produce a few bacilli.

CHEMOTHERAPY

During the past year, self-styled "science writers" have surpassed themselves in beguiling the public with a fleeting succession of hopes for a quick and

by Judd⁶⁶ for closing residual cavities following thoracoplasty. By an operative maneuver that he calls "lung mobilization and fixation," there is created a positive and forceful pressure on the cavity, and even some tension cavities can be closed by this method. With as trying a surgical problem as the tension cavity, it is good to have more than one method of approach.

A paper by Medlar and his associates⁶⁷ should prove of some aid in the surgical handling of chest diseases, since it provides for more accurate roentgenologic localization of lesions in relation to the pulmonary lobes. By employing an ingeniously constructed artificial thorax, they have obtained satisfactory roentgenograms of the interlobar septums in a variety of different positionings. They have thus devised a scheme in which the fourth and sixth costovertebral junctions serve as landmarks and by which the lobar distribution of the pulmonary disease can be readily recognized roentgenologically.

VITAMINS

The complex relation of vitamins to tuberculosis has many components, but there are two aspects that must not be confused with each other and must be discussed independently. The first is largely a problem in biochemistry, since it concerns the detection and the measurement of extent of vitamin deficiencies in tuberculous patients. The second is entirely a therapeutic problem, since it deals with the administration of vitamins for the correction of nutritional deficiencies and for the treatment of tuberculosis or its complications. To phrase the problem somewhat differently: Do vitamin deficiencies occur in tuberculosis, and if so how much can be gained by vitamin therapy? Unfortunately, a survey of the literature yields only incomplete answers to both questions at the present time.

The unqualified statement can be made that multiple vitamin deficiencies do occur in some tuberculous patients. This point has been established with reasonable certainty in spite of the facts that so-called "normal" vitamin levels are often established arbitrarily⁶⁸⁻⁷⁰ and that assays of a given patient's diet may be untrustworthy.⁷¹

Getz and his co-workers⁶⁸⁻⁷⁰ have discovered vitamin A deficiencies both by dark-adaptation tests and by blood-level estimations and, as might be expected, the deficiency of vitamin A is roughly proportional to the extent of tuberculous involvement. Breese and his associates⁷² fed measured amounts of vitamin A to 29 tuberculous patients, estimated its blood levels at given intervals thereafter, and found that in normal controls the rise of vitamin A in the blood was twice that of tuberculous patients. While admitting wide variations in single cases, the authors infer that in tuberculosis vitamin A is poorly absorbed from the intestinal tract and suggest that in this disease the diet be above average for vitamin A. An opinion has also

been expressed that tuberculous diabetic patients are in special need of this vitamin, and a daily dosage of between 150,000 and 200,000 units has been recommended.⁷³

Tuberculous persons may also be deficient in vitamin C.^{73, 74, 75} From studies on Navajo Indians, Pijoan^{71, 74} has concluded that tuberculous patients require an intake of vitamin C at least twice as great as that of normal persons to maintain a fixed plasma level of 0.7 mg. ascorbic acid per 100 cc. Pijoan⁷⁴ states, "This does not mean that vitamin C is to be specifically used in the treatment of tuberculosis as a therapeutic agent but rather as an adjunct to maintain proper ascorbic metabolism compatible with effective body economy." This confirms earlier work in which 24 patients were given 100 to 200 mg. of ascorbic acid daily, and in which it was found to be of no value in the treatment either of tuberculosis or of its complications, such as hemoptysis.⁷⁵

Nutritional studies by Farber and Miller⁷⁶⁻⁷⁸ disclose that deficiency in niacin, thiamine and vitamin K may also occur. According to these authors, hypoprothrombinemia was found to exist in 33 per cent of nonbleeding and 53 per cent of bleeding patients. The prothrombin time could be restored to normal in the majority of cases by the parenteral administration of menadione, but in spite of restoration to normal, hemoptyses often continued. Massive hemorrhages, in fact, sometimes occurred in patients with a normal bleeding time. The authors believe that it has not been established that vitamin K stops pulmonary hemorrhages or influences the course of the disease. In small hemoptyses, as Levy⁷⁹ points out, vitamin K may help to control bleeding, but evaluation of therapy for hemoptysis is a most difficult and uncertain task.

The relation of the B complex of vitamins to tuberculosis is but poorly understood. Extremely ill patients with far-advanced tuberculosis have a multitude of clinically detectable nutritional deficiencies, and some of these, it is true, are due to avitaminosis. In these extremely sick and often moribund patients, tuberculosis behaves more like a malignant process than an infectious disease, and efforts to stem the wasting of the body almost invariably end in failure.

According to Farber and Miller,^{77, 78} more than 75 per cent of acutely ill patients show some evidence of avitaminosis B. For treatment they recommend a basic supplement of 90 gm. of brewer's yeast, 150 mg. of niacin, and 6 mg. of riboflavin in divided daily doses. In specific deficiency states, up to 600 mg. of niacin, 15 mg. of riboflavin and 50 mg. of thiamine may be given daily. The authors noted some improvement in approximately 85 per cent of the patients so treated, but whether this therapeutic regime has any effect on the outcome of the tuberculosis is not stated. My own experience⁸⁰ with thiamine as a stimulant of appetite in tuberculous

use of bronchoscopy for the diagnosis and treatment of lung diseases.

Endobronchial Tuberculosis

McConkey and Gordon⁵⁹ have stressed the fact that tuberculous stenosis of major bronchi can be diagnosed clinically with an accuracy approaching 100 per cent. The cardinal symptom is wheezing. The diagnostic sign is the presence of rhonchi, occasionally audible, more frequently palpable, usually in expiration, and loudest over the stenotic bronchi. In their series of 95 tuberculous patients there were 61 who during the course of their disease developed persistent sonorous rhonchi unrelieved by cough. In 58 (95 per cent), the diagnosis of bronchial stenosis was confirmed bronchoscopically.

Lloyd and Budetti⁵⁷ have presented a comprehensive account of bronchial tuberculosis based on their experience with 475 bronchoscopic examinations. From the etiologic standpoint, they believe that tuberculosis in the parenchyma of the lung is always accompanied by changes in the mucous membrane of the draining bronchus. From the therapeutic standpoint, they find that although in some cases bronchial ulcerations heal spontaneously, cauterization is never of any value. Bronchial disease interferes more or less with drainage from the parenchymal focus, and this interference may be aggravated by collapse measures, especially pneumothorax. Hence, it is important to ascertain the state of the bronchi before attempting any collapse therapy.

A recent paper by Stone⁶⁰ gives an excellent description of the clinical aspects of endobronchial tuberculosis. In addition to wheezing and rhonchi, the author points out that the presence of an opaque or unexpandable lung during the course of pneumothorax is strongly suggestive of an underlying bronchial stenosis. Pain or soreness in the sternal region is described as a symptom in 30 per cent of the cases. Other diagnostic hints that are indicative of bronchial disease include failure of a cavity to close by thoracoplasty and clinical evidence of tuberculous bronchiectasis.

It must be remembered, however, that not all bronchial stenosis is due to tuberculosis. A fairly definite syndrome, benign nontuberculous bronchial stenosis, has been described.⁶¹

Major Surgery

Much of the recent literature on lobectomy and pneumonectomy for tuberculosis has already been reviewed by Blalock⁶² and Strieder.⁶³ Both these surgeons wisely caution that the use of resection for pulmonary tuberculosis is still in a formative stage and urge that the indications be not too rapidly extended. Time, rather than large series of cases, is necessary before the role of resection can be properly evaluated.

On the basis of their vast experience with lobectomy and pneumonectomy, Overholt and Wilson⁶⁴ have reached the following tentative conclusions: the operations are not associated with any unusual technical problems; tuberculous bronchitis or a positive pleural fluid is not necessarily a contraindication, nor is activity in the resected lung or stable (arrested) disease in the contralateral lung. Of sixty-three resections performed by Overholt from 1934 to 1943, thirty-five were pneumonectomies and twenty-eight lobectomies. The chief indication for operation was the presence of multilobar, predominantly unilateral disease. In forty-five consecutive resections since January, 1942, only 2 patients had contralateral spread; 2 had empyema, but none had a persistent fistula. In this group there were 36 reasonable-risk patients, and the operative mortality among them was 5.7 per cent. Conversion of sputum, however, was obtained in less than 70 per cent of the patients.

The ideal method for treating large cavities that remain open in spite of intensive collapse measures has not yet been found, but the progress made in this direction by Vineberg and Kunstler⁶⁵ is encouraging. They describe a method for needling such cavities and obtaining direct manometric readings of the intracavitary pressure, and they recommend that this procedure be carried out on cavities larger than 2.5 cm. before any major measure for surgical collapse is attempted. Special instruments are used for this test, and precautions are taken against complications such as empyema. On the basis of pressure determinations, Vineberg and Kunstler find that tuberculous cavities fall into three categories: those with an open bronchus and atmospheric pressure, those with a closed bronchus and negative pressure and those with check-valve mechanism and positive pressure. The last group, that of "tension cavities," has always presented a most difficult therapeutic problem, for such cavities are but little affected by surgical collapse. Negative-pressure giant cavities, on the other hand, close readily with thoracoplasty. The writers point out that it is the indiscriminate use of intracavitary drainage that has brought this valuable method of treatment into disrepute. Transthoracic intracavitary suction drainage should be employed only when a tension cavity is present, since this is the only true indication for its use. By the judicious application of suction, such cavities are reduced to the size of a catheter and can then be readily closed by thoracoplasty. The authors have performed needling of cavities in 150 cases and suction drainage in 27, without a single complication of hemorrhage, empyema, spontaneous pneumothorax or air embolism. Their valuable paper should be read by all who attempt any major chest surgery.

Almost supplementary to the methods described by Vineberg and Kunstler⁶⁵ is the technic outlined

by Judd⁶⁶ for closing residual cavities following thoracoplasty. By an operative maneuver that he calls "lung mobilization and fixation," there is created a positive and forceful pressure on the cavity, and even some tension cavities can be closed by this method. With as trying a surgical problem as the tension cavity, it is good to have more than one method of approach.

A paper by Medlar and his associates⁶⁷ should prove of some aid in the surgical handling of chest diseases, since it provides for more accurate roentgenologic localization of lesions in relation to the pulmonary lobes. By employing an ingeniously constructed artificial thorax, they have obtained satisfactory roentgenograms of the interlobar septums in a variety of different positionings. They have thus devised a scheme in which the fourth and sixth costovertebral junctions serve as landmarks and by which the lobar distribution of the pulmonary disease can be readily recognized roentgenologically.

VITAMINS

The complex relation of vitamins to tuberculosis has many components, but there are two aspects that must not be confused with each other and must be discussed independently. The first is largely a problem in biochemistry, since it concerns the detection and the measurement of extent of vitamin deficiencies in tuberculous patients. The second is entirely a therapeutic problem, since it deals with the administration of vitamins for the correction of nutritional deficiencies and for the treatment of tuberculosis or its complications. To phrase the problem somewhat differently: Do vitamin deficiencies occur in tuberculosis, and if so how much can be gained by vitamin therapy? Unfortunately, a survey of the literature yields only incomplete answers to both questions at the present time.

The unqualified statement can be made that multiple vitamin deficiencies do occur in some tuberculous patients. This point has been established with reasonable certainty in spite of the facts that so-called "normal" vitamin levels are often established arbitrarily⁶⁸⁻⁷⁰ and that assays of a given patient's diet may be untrustworthy.⁷¹

Getz and his co-workers⁶⁸⁻⁷⁰ have discovered vitamin A deficiencies both by dark-adaptation tests and by blood-level estimations and, as might be expected, the deficiency of vitamin A is roughly proportional to the extent of tuberculous involvement. Breese and his associates⁷² fed measured amounts of vitamin A to 29 tuberculous patients, estimated its blood levels at given intervals thereafter, and found that in normal controls the rise of vitamin A in the blood was twice that of tuberculous patients. While admitting wide variations in single cases, the authors infer that in tuberculosis vitamin A is poorly absorbed from the intestinal tract and suggest that in this disease the diet be above average for vitamin A. An opinion has also

been expressed that tuberculous diabetic patients are in special need of this vitamin, and a daily dosage of between 150,000 and 200,000 units has been recommended.⁷³

Tuberculous persons may also be deficient in vitamin C.^{69, 70, 74} From studies on Navajo Indians, Pijoan^{71, 74} has concluded that tuberculous patients require an intake of vitamin C at least twice as great as that of normal persons to maintain a fixed plasma level of 0.7 mg. ascorbic acid per 100 cc. Pijoan⁷¹ states, "This does not mean that vitamin C is to be specifically used in the treatment of tuberculosis as a therapeutic agent but rather as an adjunct to maintain proper ascorbic metabolism compatible with effective body economy." This confirms earlier work in which 24 patients were given 100 to 200 mg. of ascorbic acid daily, and in which it was found to be of no value in the treatment either of tuberculosis or of its complications, such as hemoptysis.⁷⁵

Nutritional studies by Farber and Miller⁷⁶⁻⁷⁸ disclose that deficiency in niacin, thiamine and vitamin K may also occur. According to these authors, hypoprothrombinemia was found to exist in 33 per cent of nonbleeding and 53 per cent of bleeding patients. The prothrombin time could be restored to normal in the majority of cases by the parenteral administration of menadione, but in spite of restoration to normal, hemoptyses often continued. Massive hemorrhages, in fact, sometimes occurred in patients with a normal bleeding time. The authors believe that it has not been established that vitamin K stops pulmonary hemorrhages or influences the course of the disease. In small hemoptyses, as Levy⁷⁹ points out, vitamin K may help to control bleeding, but evaluation of therapy for hemoptysis is a most difficult and uncertain task.

The relation of the B complex of vitamins to tuberculosis is but poorly understood. Extremely ill patients with far-advanced tuberculosis have a multitude of clinically detectable nutritional deficiencies, and some of these, it is true, are due to avitaminosis. In these extremely sick and often moribund patients, tuberculosis behaves more like a malignant process than an infectious disease, and efforts to stem the wasting of the body almost invariably end in failure.

According to Farber and Miller,^{77, 78} more than 75 per cent of acutely ill patients show some evidence of avitaminosis B. For treatment they recommend a basic supplement of 90 gm. of brewer's yeast, 150 mg. of niacin, and 6 mg. of riboflavin in divided daily doses. In specific deficiency states, up to 600 mg. of niacin, 15 mg. of riboflavin and 50 mg. of thiamine may be given daily. The authors noted some improvement in approximately 85 per cent of the patients so treated, but whether this therapeutic regime has any effect on the outcome of the tuberculosis is not stated. My own experience⁸⁰ with thiamine as a stimulant of appetite in tuberculous

children has been disappointing. As for riboflavin, decision concerning its significance must be withheld at present, since there is evidence that in some circumstances it may not be a dietary essential.⁸¹

During the last few years, McConkey⁸² has urged that cod-liver oil and tomato juice be employed in the treatment and prophylaxis of intestinal tuberculosis. From his assembled statistics it is inferred that the decline in the occurrence of this complication was coincident with the increased sale of cod-liver oil and canned citrus juices and the increased use of these preparations in his sanatorium. Be this as it may, the role of vitamin D in tuberculosis is still obscure, and accurate knowledge of its behavior is almost entirely lacking. A brief but excellent discussion of the therapeutic use of vitamin D in tuberculosis has appeared,⁸³ and it should be read before a course of vitamin D therapy is planned for the patient.

MISCELLANEOUS TOPICS

Bacteriologic technic and problems. Rapid methods have been described for concentrating and staining sputum specimens for tubercle bacilli. Reliable concentrations can be obtained by using a 5.25 per cent solution of sodium hypochlorite (Clorox) as a digestant.^{84, 85} Staining of specimens can be performed effectively at room temperature by adding propylene glycol to the staining mixture.⁸⁶ These technics should prove valuable timesavers for those laboratories already harassed by the lack of trained technicians.

The exact status of fluorescence microscopy for the detection of tubercle bacilli is still under discussion. The physical principles that underlie the method should be understood by those who attempt to use it. Laboratory studies show that it is roughly on a par with the Ziehl-Neelsen method for sputum examinations, but on gastric concentrates twice as many positive cases can be detected.⁸⁷ According to Graham,⁸⁸ fluorescence microscopy will not be ready for general use until it has been evaluated under the most favorable conditions that can be afforded by the average laboratory.

Variation in the virulence of tubercle bacilli is a problem that often plagues those working in the fields of bacteriology or immunology. Label designations may be unreliable. An approximate index of the degree of virulence can be rapidly obtained by injecting a measured suspension of weighed bacilli into the ear vein of a guinea pig.⁸⁹ Other experiments indicate that *in vitro* measurements of virulence can be obtained by culturing acid-fast bacilli with graduated amounts of diphtheria antitoxin.^{90, 91} Whether diphtheria antitoxin has any therapeutic role is not known, but some laboratory and clinical research is being conducted that may provide an answer to this question.⁹²

Virulence can apparently be altered by the presence of other micro-organisms as well as by chemi-

cals. Streptococci inoculated into rabbits seem to enhance the virulence of tubercle bacilli simultaneously or previously injected.⁹³ Avirulent human tubercle bacilli, on the other hand, have a definite retarding action on the course of the disease when injected into guinea pigs together with virulent bacilli.⁹⁴

Ultraviolet irradiation. Lurie⁹⁵ has demonstrated that in known strains of rabbits ultraviolet irradiation reduces the incidence of air-borne tuberculosis. In one set of experiments, 11 of 15 animals (73 per cent) exposed to air-borne tuberculosis in a non-irradiated room developed tuberculosis, and the disease was fatal in 9 cases, whereas not a single rabbit in the irradiated room became ill. Rabbits of low resistance as well as those of high resistance are protected by high-intensity irradiation.

Pregnancy. From a study of 26 women with advanced tuberculosis who received collapse therapy before giving birth to one or more children, Cutler⁹⁶ concludes that if the diseased area is anatomically well collapsed, the patient is afforded considerable protection against spread of the disease. Conversely, in cases in which an unsuccessful collapse is obtained, the prognosis is poor.

Congenital heart disease. When congenital heart disease complicates tuberculosis, pneumothorax is often delayed for fear of placing too heavy a burden on the cardiovascular system. That this idea is erroneous is borne out by the studies of Auerbach and Stemmerman,⁹⁷ who studied 13 such patients, 7 of whom came to autopsy and 5 of whom had pneumothorax. They state: "In view of . . . the fact that our own patients succumbed to the pulmonary involvement rather than to failure of the defective cardiovascular system, active treatment of tuberculosis is recommended. Pneumothorax induced in 5 of our patients did not lead to congestive failure in any instance."

Pneumothorax and airplane travel. By and large, persons with pneumothorax (artificial or traumatic) should be cautioned against traveling by airplane. Two well-planned articles, one published in this country⁹⁸ and the other in England,⁹⁹ point out that the moderate altitudes (5000 to 12,000 feet), usually attained by commercial airplanes are sufficient to produce a pronounced increase in the size or pressure of a pneumothorax. The risk of air travel is especially great in the presence of recently active disease, adhesions or reduced vital capacity and shortly after refills. If a patient with artificial pneumothorax must undertake a flight, he should go just before a refill, not immediately after one. An altitude of 4000 feet is regarded as the uppermost limit of safety for traumatic pneumothorax cases.

Diagnosis of early tuberculosis. In the diagnosis of early tuberculosis, even the best roentgenograms may be deceptive, since the disease actually begins as a microscopic lesion and interpretation of the

x-ray film is based on the gross appearance. Medlar and his associates^{100, 101} have presented remarkable demonstrations of this fact from both the clinical and experimental standpoints. By exhaustive laboratory studies, these authors were able to demonstrate tubercle bacilli in 2 per cent of a group of patients whose x-ray films were regarded as negative. In a subsequent series of experiments with rabbits who were intravenously inoculated with bovine tubercle bacilli, lesions were produced that could be carefully controlled and studied. Among the many important conclusions derived from this research was the fact that for a lesion to give a shadow, an area at least the size of a primary lobule must be densely packed with disease.

Vaccination with the vole bacillus. First isolated in 1937, the vole bacillus is a slow-growing Mycobacterium, apparently a third type of fixed mammalian tubercle bacillus.¹⁰² It is highly pathogenic for the vole, causes localized lesions in other laboratory animals, is innocuous to fowls, and gives no evidence that it will produce progressive disease when inoculated into man. In the experiments described by Brooke and Day,¹⁰² viable vole bacilli, heat-killed vole bacilli and Calmette-Guérin bacilli were compared in their effectiveness for protecting guinea pigs against subsequently induced experimental human tuberculosis. The results demonstrate that under the conditions established in these experiments, viable vole bacilli are at least equal, and probably superior, to Calmette-Guérin bacilli in their immunizing properties.

CASE 30521

PRESENTATION OF CASE

A sixty-two-year-old fireman was admitted to the hospital in collapse.

Two days prior to admission the patient visited the Out Patient Department because of dysuria and frequency. Rectal examination in the Urological Clinic showed a moderately enlarged, smooth, firm, nontender prostate, and catheterization revealed a residual of 330 cc. in the bladder. Because the procedure was rather traumatic, he was admitted to the Emergency Ward for two days, the stay being uneventful. Immediately following discharge, while stooping to tie his shoes, he began to sweat profusely and complained of severe precordial pain. While climbing some stairs immediately afterward he again broke out into a cold sweat, emitted a queer noise from his throat, which sounded to his wife

like a "death rattle," and, on reaching the street, vomited and collapsed. He was immediately admitted to the hospital.

The patient had been a known hypertensive for about five years, and had been complaining of dyspnea on climbing stairs, fatigability and slight ankle edema. He had taken digitalis off and on for two years. Seven months prior to admission he had visited the Nerve Clinic because of an attack of headache, vertigo, vomiting and memory loss lasting about two days and followed by a dull ache about the right ear, which was relieved by aspirin. At that time the blood pressure was 175 systolic, 100 diastolic. The heart was enlarged, with an accentuated aortic second sound, and an occasional premature beat was noted. Many moist rales were present at the lung bases. There was a constant tremor of the head and arms, which was said to have increased over a period of ten years.

The family history revealed that one brother had heart disease and another was confined in a mental institution. His mother had died at fifty-three of a "shock."

Physical examination revealed a dyspneic, deeply cyanotic man. There was an incessant tremor of the hands and head. Respirations were Cheyne-Stokes in type. Bilateral arcus senilis and retinal arteriosclerosis were present. There were sticky rales at the lung bases. The heart was enlarged, the left border being 2 cm. outside the midclavicular line. Auscultation revealed slow fibrillation, with the pulmonic second sound greater than the aortic; no murmurs were heard.

The temperature was 97.6°F., the pulse 76, and the respirations 20. The blood pressure was 110 systolic, 90(?) diastolic.

Examination of the blood revealed a red-cell count of 6,100,000, with 13 gm. of hemoglobin and a hematocrit of 62. The white-cell count was 15,600, with 82 per cent neutrophils. The urine had a specific gravity of 1.016 and a 0 to +++ test for albumin; the sediment contained 10 red cells, many

the right base. The left lung did not show this haziness. The heart was greatly enlarged in the region of the left ventricle. Examination three days later revealed marked increase in the pulmonary process (Fig. 1). The right lung was particularly dull, with numerous areas of increased density through which only little aerated lung could be seen. The hilar shadows and blood vessels were enlarged, and there was increased marking throughout the

FIGURE 1. *Roentgenogram of Chest.*

white cells and rare hyaline and granular casts per high-power field. The serum nonprotein nitrogen was 110 mg. per 100 cc., and the van den Bergh test was 0.5 mg. direct, and 1.2 mg. indirect.

On the night of admission the patient was restless and vomited several times. He was given oxygen, together with 0.19 gm. of quinidine sulfate every four hours, 0.1 gm. of digitalis a day, 0.25 gm. of sulfathiazole three times daily and paraldehyde for sedation. The following morning he vomited clear fluid containing a small amount of bright-red material. The pulse rate was 110, and he was sweating.

A portable roentgenogram of the chest revealed a hazy increase in density in the right chest that had a ground-glass appearance and was most marked at

left lung without the diffuse haziness seen on the right.

Four electrocardiograms were taken (Fig. 2), the first one on the day of admission, the second one two days later, the third one two days after that, and the last one two weeks after the third. All four electrocardiograms showed auricular fibrillation. The first one (Fig. 2A) showed, in addition, a run of regularly occurring ventricular complexes at a rate of 160 in Lead CF, with wide QRS waves; this almost certainly indicated ventricular paroxysmal tachycardia but was not shown at any other time. The first electrocardiogram also showed small, but definite, Q waves in Lead I that were of unusual shape and distinctly abnormal, along with elevated ST segments in Leads I and CF₄, in the latter the

CASE 30521

PRESENTATION OF CASE

A sixty-two-year-old fireman was admitted to the hospital in collapse.

Two days prior to admission the patient visited the Out Patient Department because of dysuria and frequency. Rectal examination in the Urological Clinic showed a moderately enlarged, smooth, firm, nontender prostate, and catheterization revealed a residual of 330 cc. in the bladder. Because the procedure was rather traumatic, he was admitted to the Emergency Ward for two days, the stay being uneventful. Immediately following discharge, while stooping to tie his shoes, he began to sweat profusely and complained of severe precordial pain. While climbing some stairs immediately afterward he again broke out into a cold sweat, emitted a queer noise from his throat, which sounded to his wife

like a "death rattle," and, on reaching the street, vomited and collapsed. He was immediately admitted to the hospital.

The patient had been a known hypertensive for about five years, and had been complaining of dyspnea on climbing stairs, fatigability and slight ankle edema. He had taken digitalis off and on for two years. Seven months prior to admission he had visited the Nerve Clinic because of an attack of headache, vertigo, vomiting and memory loss lasting about two days and followed by a dull ache about the right ear, which was relieved by aspirin. At that time the blood pressure was 175 systolic, 100 diastolic. The heart was enlarged, with an accentuated aortic second sound, and an occasional premature beat was noted. Many moist rales were present at the lung bases. There was a constant tremor of the head and arms, which was said to have increased over a period of ten years.

The family history revealed that one brother had heart disease and another was confined in a mental institution. His mother had died at fifty-three of a "shock."

Physical examination revealed a dyspneic, deeply cyanotic man. There was an incessant tremor of the hands and head. Respirations were Cheyne-Stokes in type. Bilateral arcus senilis and retinal arteriosclerosis were present. There were sticky rales at the lung bases. The heart was enlarged, the left border being 2 cm. outside the midclavicular line. Auscultation revealed slow fibrillation, with the pulmonic second sound greater than the aortic, no murmurs were heard.

*On leave of absence

The temperature was 97.6°F., the pulse 76, and the respirations 20. The blood pressure was 110 systolic, 90(?) diastolic.

Examination of the blood revealed a red-cell count of 6,100,000, with 13 gm. of hemoglobin and a hematocrit of 62. The white-cell count was 15,600, with 82 per cent neutrophils. The urine had a specific gravity of 1.016 and a 0 to +++ test for albumin; the sediment contained 10 red cells, many

the right base. The left lung did not show this haziness. The heart was greatly enlarged in the region of the left ventricle. Examination three days later revealed marked increase in the pulmonary process (Fig. 1). The right lung was particularly dull, with numerous areas of increased density through which only little aerated lung could be seen. The hilar shadows and blood vessels were enlarged, and there was increased marking throughout the

FIGURE 1. *Roentgenogram of Chest.*

white cells and rare hyaline and granular casts per high-power field. The serum nonprotein nitrogen was 110 mg. per 100 cc., and the van den Bergh test was 0.5 mg. direct, and 1.2 mg. indirect.

On the night of admission the patient was restless and vomited several times. He was given oxygen, together with 0.19 gm. of quinidine sulfate every four hours, 0.1 gm. of digitalis a day, 0.25 gm. of sulfathiazole three times daily and paraldehyde for sedation. The following morning he vomited clear fluid containing a small amount of bright-red material. The pulse rate was 110, and he was sweating.

A portable roentgenogram of the chest revealed a hazy increase in density in the right chest that had a ground-glass appearance and was most marked at

left lung without the diffuse haziness seen on the right.

Four electrocardiograms were taken (Fig. 2), the first one on the day of admission, the second one two days later, the third one two days after that, and the last one two weeks after the third. All four electrocardiograms showed auricular fibrillation. The first one (Fig. 2*A*) showed, in addition, a run of regularly occurring ventricular complexes at a rate of 160 in Lead CF, with wide QRS waves; this almost certainly indicated ventricular paroxysmal tachycardia but was not shown at any other time. The first electrocardiogram also showed small, but definite, Q waves in Lead I that were of unusual shape and distinctly abnormal, along with elevated ST segments in Leads I and CF₄, in the latter the

discontinued, since it did not appear to affect his status appreciably. He continued to fibrillate, and the lungs became almost clear to auscultation. The serum nonprotein nitrogen rose to 105 mg. per 100 cc., and the white-cell count, which had fallen to 9400, rose to 19,400. On the thirty-fifth hospital day he had a brief attack of shock, during which the blood pressure was unobtainable for a short period. He became increasingly confused, cyanotic and dyspneic and expired on the fortieth hospital day.

DIFFERENTIAL DIAGNOSIS

DR. MAURICE FREMONT-SMITH: This patient was a sixty-two-year-old man with a family history of vascular disease who manifestly had hypertensive heart disease with failure and probably some coronary disease. On the other hand he came to the hospital because of urinary symptoms and was catheterized, 330 cc. of urine having been removed from the bladder. The prostate was not thought to be large by rectal examination. One cannot tell much about urinary obstruction by rectal examination; this patient manifestly had obstruction, and long-continued obstruction can cause elevation of the nonprotein nitrogen. He left the hospital after catheterization, had some sort of an acute episode with precordial pain and then collapsed.

I believe that any one of five things could have happened to him. He might have had a coronary thrombosis, and that is perhaps the first choice. He could have had a rupture of a dissecting aneurysm, since he was a known hypertensive. Against this is the fact that the pain was anterior rather than posterior. In dissecting aneurysm pain occurs chiefly in the back between the shoulder blades or lower. In coronary thrombosis there may be pain in the back between the shoulder blades, but if present it is always associated with greater pain anteriorly. He could have had a cerebral accident, which might have caused the state of shock but could not have accounted for the precordial pain. He could have had simply a change in cardiac rhythm. Sometimes that causes precordial pain, and in a man with a poor heart, such a change in rhythm, the onset of fibrillation, for instance, may cause collapse. He could have had a pulmonary infarct, since the circulation was poor. Of course I am influenced by the fact that they tied the femoral veins; someone must have thought that he had a pulmonary infarct. The cerebral accident, with headache, vertigo, vomiting and memory loss, I cannot explain except on the basis of small cerebral thromboses, which are part of the general picture of a bad vascular situation.

The systolic blood pressure was 175, but I am quite sure that it had been higher because he was already in failure. After he came into the hospital it was 110 systolic, 90 diastolic, and he was mani-

festly in shock. He had a red-cell count of 6,000,000 and a hematocrit of 52, which indicate either concentration from dehydration or, likelier, a chronic compensatory erythremia from anoxemia, the result of heart failure. The white-cell count of 16,000 may have been due to concentration or possibly to a response to a pulmonary infarct. The urine is interesting because at one time he had no albumin and because the nonprotein nitrogen came down to normal in the hospital; both these findings argue against an actual uremia in the sense of primary kidney disease. He may have had back pressure from the prostate, which would interfere with the function of the kidneys. He certainly could have had a rising nonprotein nitrogen with myocardial infarction, owing to insufficient circulation to the kidneys. The van den Bergh test was slightly elevated, probably as a result of chronic passive congestion of the liver. He was restless and vomited several times on admission. He was given oxygen, which is reasonable, quinidine sulfate to protect him against ventricular fibrillation, which is reasonable, and digitalis.

I want to say a word about the sulfathiazole. They gave it cautiously in exceedingly small doses, probably for the urinary infection. It may have been given because the patient was on constant drainage. I should like to know about that.

DR. JACOB LERMAN: Yes; that is correct.

DR. FREMONT-SMITH: One should be particularly careful in giving sulfonamides to elderly people with bad kidneys, remembering that one may get toxic symptoms, particularly anuria, with very small amounts of sulfonamides. In any case the main thing to remember is not to give treatment that may do harm. I am interested in an article on the toxic symptoms of sulfonamides by Vilter and Blankenhorn,¹ especially the discussion by Dr. David Lehr, who has carried out animal experimentation. Dr. Lehr states that if they give plenty of alkali, animals survive very large doses of sulfadiazine; they do not get into difficulty with the kidneys, and when they are killed, no pathologic changes are found. If, on the other hand, animals that have an obstruction in the pelvis or have developed crystals are given alkali, they die rapidly. If given plain water, they die from water intoxication. Under these conditions the tubules reabsorb all the fluid and no water gets into the collecting tubules. The medication that brought about the greatest benefit in cases with a deposit of crystals were salts, either sodium chloride or a mixture of sodium bicarbonate and ammonium chloride. Apparently, if one gives a large amount of electrolytes, reabsorption from the tubules does not take place and fluids are excreted through the kidney, thus washing out the sulfadiazine crystals; but plain water or sodium bicarbonate given at the time of obstruction is detrimental. If one is going to protect a patient against sulfonamide crystalluria, apparently one should

elevation being extremely high. R waves were absent in Lead CF₄. There was slight late inversion of the T waves in Leads 1 and CF₅. There were also two ectopic ventricular contractions in other leads on this first occasion. The second electrocardiogram (Fig. 2B), taken two days later, showed a distinct change except for the auricular fibrillation. The small Q waves in Lead 1 persisted, but there were almost no R waves in that lead, and small S

low in the three limb leads. There were no R waves in Leads CF₄ and CF₅, and the ST segments were elevated in both these leads, with low T waves. In the last record, taken two weeks after the third, the record in general resembled the previous one.

Because of the possibility that a pulmonary infarction had occurred, a bilateral superficial femoral-vein ligation was performed on the second hospital day. The patient's lips remained cyanotic, and the

FIGURE 2. Electrocardiograms.

A was taken on the day of admission; B, on the third hospital day; and C, on the fifth hospital day.

waves had appeared. The T waves were slightly inverted. In Leads 2 and 3 there were distinct and striking changes: deep Q waves had appeared, the ST segments had become a little elevated, and the T waves were inverted. In the precordial leads the ST segments were within normal limits. In the third electrocardiogram (Fig. 2C), two days after that, there was an abrupt shift in the limb leads back toward the first record, in that there was no longer any Q wave in Lead 3, and Q wave in Lead 2 had become much smaller, and there was a deep wide Q wave in Lead 1. The T waves were flat to

neck veins moderately distended. On the third hospital day he complained of a "stitch" in the left chest anteriorly, just medial to the nipple, on coughing or on deep breathing. He gradually improved on a cardiac regimen augmented with oxygen. The serum nonprotein nitrogen gradually fell to normal, but the patient continued to have orthopnea, some dyspnea and moderate cyanosis. He showed a gradually increasing degree of confusion, with marked memory defect and lack of time orientation and insight.

On the twenty-sixth hospital day

gen. was

caused by an infarct and pulmonary edema. He certainly would have died immediately if the extensive lesion had been solely due to an infarct. Consequently we thought that the picture was partly caused by edema.

CLINICAL DIAGNOSES

Cardiac failure, with coronary heart disease.
Hypertension
Pulmonary infarct.
Uremia.

DR. FREMONT-SMITH'S DIAGNOSES

Hypertensive and coronary heart disease, with cardiac infarction.
Obstructing prostate (? uremia), with urinary infection.
Generalized and cerebral arteriosclerosis.
Pulmonary infarct.

ANATOMICAL DIAGNOSES

Coronary thrombosis, recent: left descending branch.
Myocardial infarct, recent: anterior wall.
Mural thrombus: left ventricle.
Thrombus occluding right pulmonary veins: left atrium.
Hemorrhage, severe: right lung.
Alveolar fibrosis: right lung.
Hydrothorax, bilateral.
Pericardial adhesion.
Chronic passive congestion with central necrosis of liver.
Nephrosclerosis, mild.
Renal infarcts.
Prostatic hypertrophy.
Urinary bladder hypertrophy, with trabeculation and pseudo diverticula.
Arteriosclerosis, severe, generalized.
Operation: femoral vein ligation, bilateral.

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: The autopsy showed an unusual condition. There was a thrombus of the descending branch of the left coronary that had produced a massive myocardial infarct in the anterior wall of the left ventricle, over which was a large mural thrombus (Fig. 3). In the left auricle was a ball-shaped thrombus, 3 cm. in diameter, which was well organized and only slightly adherent to the auricular endocardium but which could easily be pulled away leaving a not too ragged endocardial lining. This thrombus had completely plugged the openings of both right pulmonary veins, so that little blood was coming from the right lung. There was no extension of the thrombus into the veins.

The openings of the left pulmonary veins were normal. The entire right lung was dark, hemorrhagic and firm and weighed over 1000 gm., whereas the left lung was crepitant and weighed slightly under 400 gm. Certainly not much blood, if any, was coming from the right lung, which accounts for the marked contrast between the roentgenologic appearance of the right and the left lung. It is

FIGURE 3. Photograph of Heart.

intriguing to speculate how the occluding thrombus originated. There was a small and much more recent mural thrombus in the left auricular appendage that may have been the source. The occluding thrombus looked much like the mural thrombus over the ventricular infarct, but it would be rather farfetched to assume that a piece of it traveled against the current through the mitral valve into the auricle. It may have been produced merely by the auricular fibrillation.

DR. WHITE: Did the auricular myocardium look all right?

DR. CASTLEMAN: Yes; there was no infarction. We have to assume that the thrombus was there at the time of admission to the hospital because the change in the right lung was seen in the first film. Although the lungs in gross suggested infarction there were no emboli or microscopic evidence of infarction. The left lung showed slight chronic passive congestion. At first glance it looked like infarction, but all the alveolar walls were intact.

start the alkali before starting the sulfonamide; if the alkali is started later, it is not so valuable.

I shall say a word or two about paraldehyde. Paraldehyde is looked on as a safe drug, but Burstein² has reported 2 fatal cases, and by animal experimentation he found that with toxic doses animals die of right auricular dilatation. The difference between the effective dose and the toxic dose with paraldehyde is extremely slight. In psychotic patients with a good heart, paraldehyde seems to be a safe drug, but in a person with cardiac failure one should possibly think twice before giving a drug that produces fatal cardiac dilatation in animals.

Why did this patient vomit red material? Patients with chronic nephritis develop acute ulcer, and so do those with uremia. He may have had an ulcer, but it may have merely been evidence of chronic passive congestion in an old man who was vomiting.

I think that we might see the x-ray films at this time.

DR. LAURENCE L. ROBBINS: There is obvious enlargement of the heart, even though the film was not taken for the heart size, and a rather diffuse increased density throughout the medial portion of the right lung with some involvement at the base. In the first film there is nothing characteristic about the appearance. The second film (Fig. 1) shows a more diffuse process. The bronchi remain open, and the greater portion of the process appears to be within the lung. Certainly there is some fluid in the right pleural cavity, and a small amount in the left. One thing about it is that all the shadows appear to be more sharply defined than they were at the time of the previous examination.

DR. FREMONT-SMITH: Would you say that the findings are consistent with pulmonary infarcts?

DR. ROBBINS: If it is an infarct, it is a massive affair, and I should have to place the embolus in the main pulmonary artery.

DR. FREMONT-SMITH: Do you think that it is a diffuse bronchopneumonia?

DR. ROBBINS: I do not know. It does not look characteristic of anything. It could be consolidation throughout the lung, with bronchopneumonia as a terminal affair, but this film was taken some time before he died. So far as I am concerned it could be a massive infarct or a diffuse pneumonia, with a small amount of pleural effusion on each side.

DR. FREMONT-SMITH: That is certainly consistent with the diagnosis of pulmonary infarct.

DR. ROBBINS: If it is an infarct, it is the largest one that I have seen.

DR. FREMONT-SMITH: An infarct of that size should have been immediately fatal. I wish that Dr. White would discuss the electrocardiograms, which are beyond my depth. I should like to know whether the electrocardiograms differentiate pulmonary infarct and coronary disease. I should say

that this patient had coronary disease, whether recent or old I do not know.

DR. PAUL D. WHITE: The electrocardiograms are extremely interesting. One of the most significant findings is not the auricular fibrillation but the other disturbance of rhythm found on the first day, namely, the probable ventricular paroxysmal tachycardia which strongly suggests myocardial infarction or the toxic effect of digitalis. Furthermore, the variations in the QRS waves, ST segments and T wave in the limb and precordial leads are also particularly significant and confusing. The first (Fig. 2A) third (Fig. 2C) and fourth electrocardiograms are absolutely characteristic of the effect of anterior myocardial infarction, as shown by the Q waves in Lead I, the absence of the R waves in Leads CF₁ and CF₂, and the ST segment elevations in Leads I, CF₁, and CF₂. We might have expected, however more definite inversion eventually of the T wave in Leads I, CF₁, and CF₂, which did not develop during the time in which these electrocardiograms were taken.

The second electrocardiogram (Fig. 2B), taken two days after admission, is the one that is the most interesting because of the abrupt temporary but striking differences from the first and the later electrocardiograms. Here the findings suggest those either of posterior myocardial infarction or of an acute cor pulmonale superimposed on some effects of the anterior myocardial infarction. The deep Q waves, the inversion of the T waves in Leads 2 and 3 and the small S waves in Lead 1 make one think of a cor pulmonale. The effect is, in the main, temporary, and the T waves in Leads 1, CF₁, and CF₂ may have failed to become inverted in later records, owing to the increased pulmonary pressure. Thus, the electrocardiograms show a complicated condition either in the form of multiple involved myocardial areas or in the form of a combination of the factors of myocardial infarction and of acute cor pulmonale.

DR. FREMONT-SMITH: I think that this patient had hypertensive and coronary heart disease, with cardiac infarction and probably pulmonary infarction, obstructing prostate and urinary infection. There may have been a terminal bronchopneumonia as well; and there was, of course, generalized arteriosclerosis and cerebral arteriosclerosis.

DR. LERMAN: I should like to make a few comments in answer to some of the questions raised by Dr. Fremont-Smith. The mental state was probably due to anoxemia. The patient was always cyanotic and markedly orthopneic. I can visualize him tossing around in bed in a disoriented manner. The bizarre nitrogen fluctuations undoubtedly were due to the fact that he pulled out his catheter every so often. Whenever he did that, he became obstructed and the nitrogen values rose. I do not know the exact interpretation of the unusual x-ray changes, but as I recall it the explanation was that they were

progressively worse and were associated with weakness, anorexia and loss of weight. About nine months prior to entry, in spite of her increasing symptoms, the patient was married. Following marriage, she appeared to improve somewhat but soon developed a cold, associated with an exacerbation of her symptoms. She had lost 18 pounds since the beginning of her illness, dropping from 116 to 98 pounds, and because of increasing weakness she entered a community hospital. The red-cell count was said to have been 2,600,000. After five weeks of symptomatic treatment, augmented by transfusions, she was discharged considerably improved, the red-cell count having risen to 4,300,000. She was sent to a convalescent home, where she gained weight and strength. The diarrhea had practically ceased and there was no blood in the stools. One month later, about five and a half months before admission, she developed a sharp, stabbing pain in the right upper thorax just below the shoulder, made worse by respiration. The pain lasted about a week and was treated by diathermy. Shortly thereafter she developed severe bloody diarrhea and was again hospitalized. A sigmoidoscopic examination at that time was said to reveal "pinpoint ulcers that bled easily." She suffered severe abdominal pain, requiring morphine for relief. Four months before entry she was transferred to another hospital, at which time she was bleeding profusely by rectum and appeared almost in extremis. She complained of cough, which was accompanied by a small amount of white frothy sputum and chest pain, and was running a low-grade, undulating fever without chills. There was no hemoptysis. A roentgenogram of the chest revealed elevation of the right half of the diaphragm and increased density over the entire right lung; the latter was interpreted as being due to pleural effusion, but several taps were unsuccessful. The left chest was clear. A loop ileostomy was performed, and a spontaneous ileostomy developed proximal to the operative ileostomy two weeks later. In spite of the ileostomy, numerous transfusions and nearly 1,000,000 units of penicillin, the patient showed no improvement and had several major hemorrhages by rectum. About one and a half weeks before entry she had a sudden attack of dyspnea and cyanosis, with a temperature of 105°F., apparently following an injection of penicillin. The next day the temperature was 95°F., and she subsequently improved rapidly.

The patient was born in Oklahoma and had lived there until shortly before the onset of her illness. She had had three attacks of rheumatic fever at the ages of seven, nine and seventeen years, respectively, without apparent sequelae.

Physical examination revealed an extremely weak, lethargic, markedly cachectic woman. The skin was cold, dry and pale, with little subcutaneous fat. The skin around the ileostomy openings was inflamed, undermined and tender. The scars of several

decubitus ulcers were present. There was an infected area over the sternum, apparently the site of a bone-marrow infusion. The chest was small and sunken, with marked splinting on the right. The lower half of the right chest was dull to percussion anteriorly and posteriorly, and breath sounds over this area were diminished to absent. Elsewhere on the right the breath sounds were bronchovesicular with numerous coarse inspiratory rales. The left chest was clear. There was a rough apical systolic murmur obliterating the first sound. There were flexion contractures of both legs and slight clubbing of the fingers.

The temperature was 100°F., the pulse 90, and the respirations 25. The blood pressure was 80 systolic, 40 diastolic.

Examination of the blood revealed a red-cell count of 4,000,000, with 55 per cent hemoglobin, and a white-cell count of 9000, with 70 per cent neutrophils and 30 per cent lymphocytes. The urine was essentially negative. The blood serum nonprotein nitrogen was 21 mg. per 100 cc., the protein 4.9 gm., with an albumin-globulin ratio of 1.4, and the chloride 89-99 milliequiv. per liter. The van den Bergh test was 1.1 mg. per 100 cc. direct, and 1.8 mg. indirect. The prothrombin time was 38 seconds (normal, 18 to 20 seconds). A tuberculin test in a dilution of 1:1,000,000 was negative.

A roentgenogram of the chest (Fig. 1) revealed a miliary process scattered throughout both lung fields, with dense consolidation in the middle lobe on the right and evidence of some consolidation in the right lower lobe. The right half of the diaphragm was not clearly visualized. There appeared to be a cavity in the posteroinferior portion of the right lower lobe that was connected with a bronchus. The heart and mediastinum appeared to be in normal position, and the liver and spleen were enlarged.

The patient was given transfusions, infusions and penicillin. On the second hospital day she developed sudden dyspnea and cyanosis, with distended neck veins and many inspiratory rales and wheezes. The pulse was 120, and the respirations 35. Following the use of tourniquets, oxygen and Cedilanid she improved rapidly. The following day examination revealed moderate edema of the lower extremities. There was no engorgement of the neck veins. The point of maximum cardiac impulse was felt 2 cm. beyond the midclavicular line. The heart rhythm was regular, with a diastolic gallop. The second pulmonic sound was extremely loud, and there was a questionable mid-diastolic rumble at the apex. An electrocardiogram showed rather low T waves but nothing of definite diagnostic value. The patient continued to run a fever between 100 and 103°F. A spasm of coughing on one occasion was productive of a small amount of bloody sputum that was negative on smear for acid-fast organisms. She had several attacks of pulmonary edema similar

and the alveoli were filled with blood. The other striking thing in the right lung and not in the left was the presence of numerous areas of fibrosis within the alveoli (Fig. 4), a picture that Masson³ has described in rheumatic pneumonia. It occurred to me that perhaps these fibrous plugs should not be ascribed to rheumatic pneumonia but to pulmonary

to state that any electrocardiographic findings are pathognomonic, but we can almost surely say that prominent Q waves in Lead 1, especially when carried over to Lead 2, are rarely found in any condition other than anterior myocardial infarction. (If Lead 1 is upside down, owing to congenital dextrocardia, that is another thing.

FIGURE 4. Photomicrograph of Lung Showing Intra-Alveolar Fibrosis.

hypertension, since they were not present in the other lung. We know that most rheumatic patients have mitral stenosis with pulmonary hypertension, and perhaps we have here a clue to the cause of so-called "Masson bodies." There were no hyaline membranes of the alveoli, another finding in some cases of rheumatic pneumonia.

DR. WHITE: Do you know of a similar case in the literature? I have never heard of one.

DR. CASTLEMAN: No.

Another finding was a hypertrophic and trabeculated bladder due to prostatic enlargement, with no evidence of distention of the renal pelves or pyelonephritis. There were a few renal infarcts, which must have been produced by emboli from the mural thrombus in the heart. There were also thrombi in the deep veins in the legs, but none of these could have reached the lungs because of the bilateral femoral-vein ligation.

DR. WHITE: I should like to make a further comment about the electrocardiograms. We hesitate

CASE 30522

PRESENTATION OF CASE

A twenty-year-old married woman was admitted to the hospital with persistent diarrhea.

The patient was perfectly well until a year prior to admission, when she had an attack of "intestinal grippe," with abdominal pain, malaise and cough, which was productive of phlegm but not of blood. After a few days she again felt well. About two months later she first noted some red streaking at stool and had a mild diarrhea. A local physician was consulted, and she was treated for hemorrhoids, without effect. The diarrhea and bleeding became

persistent ulcerative lesion in the colon, definite evidence of pulmonary disease. The interpretation of the type of pulmonary disease is particularly difficult unless the density was greater than I assumed that it was; slight density over the entire chest is rather unusual if due simply to pleural effusion. The absence of a large pleural effusion seems to have been borne out by the fact that taps were unsuccessful. From that time until death the pulmonary disease increased rather steadily. Perhaps this is the best time to see the x-ray films.

that the patient probably had rheumatic heart disease with mitral involvement, a sequela of the three attacks of rheumatic fever. Whether or not the attacks of pulmonary edema that came on acutely on several occasions during the last few days of her life were related to the underlying cardiac disease is impossible to say. It would be unusual to have these symptoms if cardiac failure were secondary to the pulmonary involvement. The question whether a rheumatic myocarditis was also present at that time cannot be answered,

FIGURE 2.

DR. MILFORD SCHULZ: The film of the chest taken shortly after entry shows a densely consolidated area in the lower part of the right lung, in which there apparently is an abscess cavity. The miliary process throughout the lungs did not change much during her stay, but the whole right lung became denser, as recorded. It is curious that the bronchi within the consolidated lung contain air. The lung apparently was "drowned." The cavity is not apparent on the second film.

DR. ROPES: We have then two major processes — a severe ulcerative disease of the colon and a pulmonary lesion consisting of a miliary process, marked consolidation and probably cavitation. In addition, I believe that the cardiac findings indicate

although it must be considered. Evidence of other systemic involvement is apparent. Hepatic dysfunction is indicated by several findings — the elevated van den Bergh, the high prothrombin time and the definite, although not marked, abnormality of the serum protein. The clubbing of the fingers could have been secondary to the ulcerative disease in the colon or to the pulmonary disease, possibly accentuated by both. The contractures of the legs are of interest. In general such flexion contractures rarely develop except in the presence of active joint disease or after prolonged immobilization. There was no immobilization in this case, but I hesitate to introduce an element of joint disease.

The case really comes down to the question

to the first, all of which responded promptly to therapy. A proctoscopy revealed a rough bleeding mucosa with many pseudopolyps. Another roentgenogram of the chest on the ninth hospital day (Fig. 2) revealed a marked change, the right lung appearing completely consolidated. Several bronchi in the right lung were seen to contain air, and the miliary process in the left lung had somewhat increased. X-ray examination of the abdomen revealed no evidence of dilated loops; there was enlargement of the spleen, but no definite enlarge-

even at the onset, or soon thereafter, respiratory symptoms were apparent. If the attack of intestinal gripe marked the beginning of the disease, respiratory symptoms appeared at the onset. The first persistent symptom came some two months later and was wrongly diagnosed. The patient had blood in the stools; this was considered of little significance and was thought to have been due to hemorrhoids, which may or may not have been demonstrated. No further attempt was made to find the cause. Since she had diarrhea associated with the blood,

FIGURE 1.

ment of the liver. Examination of the fundi showed venous stasis and slight papilledema but no tubercles or infarcts.

On the thirteenth hospital day, the patient expired.

DIFFERENTIAL DIAGNOSIS

DR. MARIAN ROPES: In this patient of twenty I think it is probably going to be necessary to make two diagnoses, possibly more. Some, or perhaps most, of the anatomic and physiologic changes are relatively apparent, but the etiology is much less obvious. During the first part of the disease the predominant feature was evidence of an ulcerative lesion of the colon. It is significant, however, that

it is even more surprising that no further search was made at that time. Shortly, however, the severity of the disease became apparent, and at the time of her first admission to a hospital the entire picture can be said to have been consistent with idiopathic ulcerative colitis, which appeared to respond rather well to treatment.

The first definitely atypical symptom was the attack of severe pain in the chest. Again, no attempt was made to determine the cause of the pain. It was treated with diathermy and apparently was of short duration. Both the gastrointestinal symptoms and the respiratory symptoms increased steadily, however, and at the time of the second admission to the outside hospital she had, in addition to a

The joint disease is of interest. About 10 per cent of patients with ulcerative colitis have rheumatoid arthritis. It is an important finding, since it complicates treatment.

This case was hopeless from the beginning, but it seemed to me that we had to give her the benefit of the doubt and try to approach the problem from the point of view of potential colectomy. She was too serious a risk to tolerate major surgery. She died of pulmonary disease, accompanied by active colitis. I do not know anything about coccidiosis of the bowel. I suppose it can occur, but I have never seen a case. I am inclined to doubt that this was a case of coccidiosis of the lung and bowel.

DR. ROPES: Did she have severe diarrhea in the hospital?

DR. JONES: She had constant rectal discharge part of the time, but it let up. We have seen that with extensive involvement of the entire bowel. I was impressed that she did not have marked spasm of the abdominal wall.

DR. LELAND S. MCKITTRICK: Dr. Jones mentioned the possibility and hope of a colectomy in this woman. This has been done in a certain number of desperately ill patients with success. Dr. Daniel F. Jones taught years ago that, if one is able surgically to remove the cause of the illness, the desperately sick patient will tolerate major surgery. In ulcerative colitis one of the basic principles in following out that dictum is the elimination of other conditions or complications, so that when colectomy is done the factor that has been making the patient sick is removed. When the lung condition became apparent in this patient, no attempt was made to remove the colon.

CLINICAL DIAGNOSES

Chronic ulcerative colitis.

Pulmonary tuberculosis?

DR. ROPES'S DIAGNOSES

Granulomatous disease of lungs (? coccidiosis, ? tuberculosis).

Ulcerative colitis (? coccidiosis, ? tuberculosis, ? idiopathic).

Rheumatic heart disease, with mitral involvement.

ANATOMICAL DIAGNOSES

Pulmonary tuberculosis.

Miliary tuberculosis: lung, spleen, liver and kidneys.

Tuberculous peritonitis.

Chronic ulcerative colitis, idiopathic.

Rheumatic heart disease, with mitral stenosis.

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: The autopsy on this woman showed a diffuse process involving the entire colon up to the ileocecal valve; it was characteristic of the healing stage of idiopathic chronic ulcerative colitis. There were, as Dr. Jones mentioned, pseudopolyps with attempted bridging of the mucosa over the previously ulcerated areas. We found no evidence of acute ulcers in the colon; we took about a dozen sections and I could not find a really good ulcer, the epithelium having regrown over the ulcerations. The mucosa, submucosa and muscularis of the bowel showed nonspecific chronic inflammation but no evidence of any other process. The serosa of the bowel, both large and small, was studded with tubercles, so that there was a diffuse tuberculous peritonitis without ascites, which perhaps accounted for the pain and tenderness, as well as the slough around the ileostomy. The process in the lungs was due to active tuberculosis, and there was a miliary spread involving practically every organ of the body. I do not believe that there was any etiologic relation between the ulcerative colitis and the tuberculosis; that is, she had two separate diseases. I am confident that, if she had not developed tuberculosis, the ulcerative colitis could have been cured by colectomy, because it was not so severe a grade of colitis as we often see. Dr. Jones has asked me to hazard a guess concerning when the miliary spread started. I really do not know, but it might have been at the time she developed pain in the chest, about five months before admission.

DR. JONES: What did the heart show?

DR. CASTLEMAN: There was definite old rheumatic involvement of the mitral valve, with a moderate degree of stenosis but no evidence of activity.

A PHYSICIAN: It might be worth while to mention that during the two weeks in this hospital there was practically no discharge from the rectum.

DR. CASTLEMAN: That would fit in with our findings in the colon.

DR. MCKITTRICK: I should like to add a comment to what Dr. Jones said; that is, one cannot depend on the absence of rectal discharge or of diarrhea as evidence of a quiescent ulcerative colitis. I recently had a patient with a fever of 102 to 103°F. and a hemoglobin of 8 gm. or below over a period of weeks who had one formed, guaiac-negative movement a day. Ileostomy and later colectomy were necessary to cure the patient. What Dr. Jones says is correct. The essential thing is to exclude evidence of anything else that can cause fever, debility, anemia and so forth.

The house staff is to be congratulated for finding this pulmonary condition. It looks obvious in the x-ray films, but when you saw this young woman it was a different story.

whether the pulmonary lesion and the ulcerative disease of the colon were due to the same etiologic agent, and if they were, what was the agent. The possibility that malignant disease was the explanation of this entire picture is extremely unlikely. On the other hand, various types of infection ought to be considered. One that is likely to give lesions of this type is tuberculosis. There are many unusual features, however. If the disease was primary in the lungs, which one must assume, the early onset of relatively severe colitis is unusual. The co-existence of a miliary process during the period of marked progression of the consolidation of the lobes is also atypical. Furthermore, the failure to find organisms is most unusual, although not impossible. Unfortunately, we are told the result of only one sputum examination. Possibly the patient did not raise sputum at any other time; but that is definitely unlikely because we know that early in the course of the disease she was raising sputum. The blood-cell counts and the differential are consistent with tuberculosis, but do not aid greatly in making the diagnosis. If the colitis was due to tuberculosis I should not expect a marked improvement during the early stage, with severe colitis thereafter. Again, this does not rule tuberculosis out, but it is unusual.

The possibility of parasitic infection must be considered, but I am unable to think of a parasitic or fungus infection to explain the whole picture. The one diagnosis that should possibly be considered is coccidiosis. The patient came from Oklahoma, which is included in the region where coccidiosis has been seen quite frequently. Coccidiosis can explain pulmonary lesions of this type. As I came into the room I asked Dr. Chester Jones whether he had heard of coccidiosis associated with ulcerative colitis. He said that he had not, but I wonder if this is one of the cases of diffuse involvement that are occasionally seen in this disease. The liver disease here might be ascribed to that.

In summing up the situation I shall conclude that the pulmonary lesions and the ulcerative disease of the colon were probably related. I expect that granulomatous lesions were found, perhaps not due to tuberculosis but possibly, although not likely, due to coccidiosis. Idiopathic ulcerative colitis in addition to the pulmonary disease is a possibility. I also believe that the patient had rheumatic heart disease with mitral involvement.

DR. CHESTER M. JONES: I saw this patient in the outside hospital before she was transferred here. She was a desperately sick woman at that time, and it was obvious that the chances of recovery were extremely slight. She had an ulcerative colitis that had progressed rapidly in spite of ileostomy, presumably done at the proper time. In addition she still had evidence of active ulcerative colitis, as indicated by diarrhea. She was markedly undernourished and greatly depleted, even after intensive treatment. We tried to cover the obvious deficien-

cies in various ways — vitamins, protein and so forth. The ileostomy was functioning but was surrounded by a sloughing area.

At that time the pulmonary situation was not apparent. My belief was that she probably had an idiopathic ulcerative colitis, because of the rather characteristic course. It started out as a relatively mild affair, with exacerbations and remissions, and then became much worse under conditions that were favorable for its progress. She was an extremely apprehensive person. She had been separated from her husband part of the time and the whole situation was difficult for her. Such a psychic background is a factor in ulcerative colitis and must always be taken into account.

When I examined her, there was tenderness in the flank, with slight rigidity. I thought that there was marked cellulitis of the bowel wall and was afraid that there might have been perforation. The prognosis appeared hopeless unless it was possible to take out the diseased colon, a major problem that could be done only as a desperate final move.

The experience with penicillin is of interest. During the last two years we have found that penicillin is of practically no value in ulcerative colitis. In one case that I have seen there was a brilliant result from its use, but in other cases there has been no favorable response.

The clubbing of the fingers was not unusual for this grade of chronic diarrhea, as Dr. Ropes has pointed out, although the mechanism of its production is not understood. The prolongation of prothrombin time is another common finding in serious diarrhea. We have seen two or three cases of infection in the liver itself as a result of ulcerative colitis, but it is rare. Enlargement of the spleen is not uncommon.

One point cannot be too heavily stressed: the treatment of hemorrhoids because of rectal bleeding without an adequate investigation must be avoided. I believe the rule still holds on the surgical service that a hemorrhoidectomy for bleeding is not permitted until sigmoidoscopy is done. Is that correct, Dr. Allen?

DR. ARTHUR W. ALLEN: Yes.

DR. JONES: That is a tremendously important dictum. This woman was treated for hemorrhoids because of the bleeding, when, as a matter of fact, the bleeding was due to ulcerative colitis. Experience has taught us that any local treatment tends to light up the disease.

I should doubt very much that these ulcers were tuberculous. The ulcerations of tuberculous colitis are usually sluggish, punched-out lesions with undermined edges. If one saw them in the rectum it would mean extensive disease, and in a severely ill patient one would expect the ulcerations to be typical. Here, apparently they were not. There was a large area of mucosa covered with pseudopolyps, with characteristic bleeding.

The joint disease is of interest. About 10 per cent of patients with ulcerative colitis have rheumatoid arthritis. It is an important finding, since it complicates treatment.

This case was hopeless from the beginning, but it seemed to me that we had to give her the benefit of the doubt and try to approach the problem from the point of view of potential colectomy. She was too serious a risk to tolerate major surgery. She died of pulmonary disease, accompanied by active colitis. I do not know anything about coccidiosis of the bowel. I suppose it can occur, but I have never seen a case. I am inclined to doubt that this was a case of coccidiosis of the lung and bowel.

DR. ROPES: Did she have severe diarrhea in the hospital?

DR. JONES: She had constant rectal discharge part of the time, but it let up. We have seen that with extensive involvement of the entire bowel. I was impressed that she did not have marked spasm of the abdominal wall.

DR. LELAND S. MCKITTRICK: Dr. Jones mentioned the possibility and hope of a colectomy in this woman. This has been done in a certain number of desperately ill patients with success. Dr. Daniel F. Jones taught years ago that, if one is able surgically to remove the cause of the illness, the desperately sick patient will tolerate major surgery. In ulcerative colitis one of the basic principles in following out that dictum is the elimination of other conditions or complications, so that when colectomy is done the factor that has been making the patient sick is removed. When the lung condition became apparent in this patient, no attempt was made to remove the colon.

CLINICAL DIAGNOSES

Chronic ulcerative colitis.

Pulmonary tuberculosis?

DR. ROPES'S DIAGNOSES

Granulomatous disease of lungs (? coccidiosis, ? tuberculosis).

Ulcerative colitis (? coccidiosis, ? tuberculosis, ? idiopathic).

Rheumatic heart disease, with mitral involvement.

ANATOMICAL DIAGNOSES

Pulmonary tuberculosis.

Miliary tuberculosis: lung, spleen, liver and kidneys.

Tuberculous peritonitis.

Chronic ulcerative colitis, idiopathic.

Rheumatic heart disease, with mitral stenosis.

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: The autopsy on this woman showed a diffuse process involving the entire colon up to the ileocecal valve: it was characteristic of the healing stage of idiopathic chronic ulcerative colitis. There were, as Dr. Jones mentioned, pseudopolyps with attempted bridging of the mucosa over the previously ulcerated areas. We found no evidence of acute ulcers in the colon: we took about a dozen sections and I could not find a really good ulcer, the epithelium having regrown over the ulcerations. The mucosa, submucosa and muscularis of the bowel showed nonspecific chronic inflammation but no evidence of any other process. The serosa of the bowel, both large and small, was studded with tubercles, so that there was a diffuse tuberculous peritonitis without ascites, which perhaps accounted for the pain and tenderness, as well as the slough around the ileostomy. The process in the lungs was due to active tuberculosis, and there was a miliary spread involving practically every organ of the body. I do not believe that there was any etiologic relation between the ulcerative colitis and the tuberculosis; that is, she had two separate diseases. I am confident that, if she had not developed tuberculosis, the ulcerative colitis could have been cured by colectomy, because it was not so severe a grade of colitis as we often see. Dr. Jones has asked me to hazard a guess concerning when the miliary spread started. 1945

THE year of decision that was 1944 has joined the procession of the past, and the year of decision 1945 becomes our present and immediate future. Again we are faced with the promise of a credit of days to be put to use before the current annual allotment expires, and again we are confronted with certain goals that we hope to attain before the new year becomes another old one.

The year 1944, although one of decision, was certainly not our year of fulfillment. In 1944, it is true, we launched mighty offensives on land and sea, but the final decision is not yet in sight, and we have come to a realization of other facts associated with our great effort, to an appreciation of the possibility that war can bring us the extremes in human con-

duct—great sacrifices and great suffering on the one hand, and great selfishness and great indulgence on the other.

At a period when millions of our countrymen are putting in jeopardy their chief possession, and casualty lists are mounting, many thousands of others are maneuvering for a greater share of the restricted necessities of life, are bargaining for ignoble luxuries, are deserting essential industries and are strangers to that spirit of sacrifice without which a cause cannot be wholly won.

We will learn, in the year that we are entering, some useful and some chastening lessons. We will come with reluctance to a full appreciation of the fact that we are engaged in the most momentous and the bloodiest war of our history. We will realize, after three years in arms, that the early warnings of the experts were well founded, and that this time there is no easy road to victory, no slick trick by which the days of peace can be restored to us. We will be taught, perhaps in this year and certainly in the years to come, that the ending of war may bring practically anything but peace, for there can be no peace with cruelty, hatred and evil, or while there is still anything to fight for.

We will learn, by an experience that living generations have never yet encountered, that when a democracy goes to war it can win only with the full support of its people, that every individual must participate and that the extent and the speed of the victory are determined by the effort that is made. We may hope also that those in authority will finally learn that it pays to keep faith with the public, that in the long run truth pays better dividends than does propaganda and that any partnership must be based on mutual confidence.

Certain words of Paul to the Corinthians may be taken to heart also by all Americans, "He which soweth sparingly shall reap also sparingly; and he which soweth bountifully shall reap also bountifully."

CHEMOTHERAPY OF TUBERCULOSIS

TUBERCULOSIS is one of the diseases that is usually considered as not being responsive to sulfonamide drugs. At present it is also being listed among the

conditions in which penicillin is ineffective. Because of the nature of this infection and its great prevalence, it is easy to understand why the lay press continually plays up any encouraging news concerning agents that possibly have a curative effect in the disease. If, however, such agents must be used for a long time and under conditions that are themselves not without danger to the health and life of the patient, such unwarranted publicity may cause considerable harm.

Many physicians throughout this country, particularly those interested in pulmonary diseases, have been considerably annoyed in recent months by the publicity given to one of the newer chemotherapeutic agents that is now being investigated in experimental tuberculosis and in human clinical cases. Indeed, the members of the American Trudeau Society, a group of eminent physicians with particular interest in the treatment of pulmonary tuberculosis, have considered this matter to be serious enough to warrant a special report by its Committee on Therapy. This report, which was presented at a meeting of the Medical Section of the National Tuberculosis Association on March 17 and 18, 1944, was published in the April issue of the *American Review of Tuberculosis*. It should serve to clarify the position of experts concerning the present status of the therapeutic agents under investigation. The following is quoted from this report:

It is the opinion of the committee that the clinical and roentgenological data so far made available to the committee on the action of Diasone on human tuberculosis are as yet inadequate, both quantitatively and qualitatively, to permit, even tentatively, a positive evaluation of its curative effects upon tuberculosis in humans. The committee believes that there is, at this time, no adequate basis for the optimistic implications of the magazine articles or of the releases to the press which are now so well known to both the profession and public. It is believed, on the contrary, that such implications are distinctly unwarranted and not in accord with the clinical evidence which has been reviewed by the committee. The committee regrets exceedingly that the magazine articles mentioned previously were published in spite of efforts on the part of both the committee and the clinician to stop their publication.

Until controlled studies of a definite scope have been reported, it is recommended that none of these drugs be used for treating tuberculous patients except under conditions which will appreciably add to our knowledge of their clinical action, and in the presence of adequate facilities to protect patients effectively from their potentially serious toxic

Patients and physicians must also be

reminded of the provisions of the federal regulations which prohibit the distribution of a drug in the experimental phase of development to other than research institutions to which the material is assigned by the manufacturer for either laboratory or clinical investigation. The committee is informed that other clinical investigations are now in progress, and it is the expressed opinion of the committee that such further well-controlled clinical investigation is distinctly desirable.

Any use of chemotherapeutic agents, including Diasone, in the treatment of tuberculous patients, must, therefore, be regarded as purely a project in clinical investigation. It must be again emphasized that such use is not without hazard and that the roentgenological and clinical evidence reviewed by the committee gives no justification at this time for any attitude concerning the value of these drugs in patients other than one of critical interest.

It is of interest that the same issue of the *American Review of Tuberculosis* contains a paper by Petter and Prenzlau, entitled "Treatment of Tuberculosis with Diasone," which was presented before the Mississippi Valley Trudeau Society in September, 1943. It is followed by a discussion by Dr. C. H. Hinshaw, who, interestingly enough, is the chairman of the Committee of Therapy of the American Trudeau Society. In his remarks, Dr. Hinshaw mentions several reports from Great Britain and the United States that suggest that Promin, another and similar chemotherapeutic agent, may have some therapeutic value. These reports, he adds, are encouraging, but he emphasizes that conclusive proof of efficacy in clinical tuberculosis is lacking for both Promin and Diasone. He also calls attention to the unpredictability of tuberculosis and to its marked tendency to heal without treatment, both of which, to be excluded, require rigid control. He also mentions studies carried out at the Mayo Foundation, which indicate that Diasone is less effective than Promin in experimental tuberculosis in guinea pigs. The Mayo workers also have found that both these drugs are more toxic to human beings than to guinea pigs. These toxic effects may be disturbing and even alarming, although they are usually controllable, unless there is an idiosyncrasy, by properly regulating the dosage. The slow rate of excretion of these drugs necessitates the greatest care in their use.

Petter and Prenzlau report observations on the use of Diasone in 44 patients with human tuberculosis who received an average of 0.9 gm. daily for an average of one hundred and fifty-six days.

They noted some degree of improvement in all the minimal and moderately advanced cases and in 79 per cent of far-advanced cases. Sputum conversion occurred in 59 per cent of all cases, and cavities closed during treatment in 43 per cent. They discuss the general reactions that were observed and emphasize the need for careful clinical and laboratory observations during the administration of the drugs. They believe that their findings point the way to further advances in the treatment of tuberculosis in man.

In a discussion in the May '26 issue of *Science*, under the title "The Paper Shortage and Scientific Publication," Griggs proposes early publication of abstracts or making promptly available in the form of microfilms all scientific papers as soon as they are received for publication. This, he feels, would serve the important purpose of acquainting scientists regarding the results of research by fellow workers. This, in turn, would help them in the conduct of their own studies and would have a tendency to reduce duplication of effort. So far as this discussion concerns scientific journals as a means of keeping research workers informed, there is much to be said in favor of these proposals.

Griggs goes on to stress the contributions of such abstracting magazines as the *Reader's Digest* to the field of literature. There is much to be said in favor of this argument. This type of magazine and other lay magazines may, in addition, render a useful service in popularizing some of the leading medical and scientific advances. It may not be entirely safe or desirable, however, to entrust these lay magazines with the premature announcement of great scientific discoveries in the field of medicine. Their function could best be served only after adequate and thorough discussion of the value of these discoveries by competent investigators in the field has proved beyond a doubt the value of the discoveries that they wish to popularize.

It is highly desirable that, in the future, such magazines try to avoid doing the disservice that has, in the past, resulted from rosy pictures prematurely painted concerning proposed remedies that are only in the process of being clinically evaluated. Such publication later results in serious disillusionment to the afflicted persons who seek relief, and not in-

frequently adds to their suffering, in addition the considerable expense to which they may put in the process.

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

GRIMES — Warren P. Grimes, M.D., of Hillsboro died November 13. He was in his seventy-seventh year. Dr. Grimes received his degree from Harvard Medical School in 1891. He was a member of the New Hampshire Medical Society and the American Medical Association. His widow survives.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	CLINIC CONSULTANT
Haverhill	January 3	William T. Green
Lowell	January 5	Albert H. Brewster
Salem	January 8*	Paul W. Hugenberger
Brockton	January 11	George W. Van Gorp
Pittsfield	January 15	Frank A. Slowick
Springfield	January 17	Garry deN. Hough
Worcester	January 19	John W. O'Meara
Hyannis	January 23	Paul L. Norton
Fall River	January 29*	Eugene A. McCarthy

*Day changed.

NOTICES

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the of the New England Hospital for Women and Children be held on Thursday, January 4, at 7:15 p.m., in the room of the nurses' residence. Dr. Miriam G. Katzeff speak on the subject "Postmenopausal Osteoporosis."

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINN THURSDAY, JANUARY 4

FRIDAY, JANUARY 5

*9:00-10:00 a.m. Cancer of the Cervix. Dr. B. Lorincz. Joseph Pratt Diagnostic Hospital.

10:50 a.m. Benign New Growth. Dr. E. Lafreniere. (Postgraduate clinic in dermatology and syphilis.) Dowling Amphitheater Boston City Hospital.

12:00 m.-1:00 p.m. Clinicopathological conference. Boston Floating Hospital. Held in Lecture Hall of Joseph H. Pratt Diagnostic Hospital.

SATURDAY, JANUARY 6

*10:00 a.m.-12:00 m. Medical staff rounds. Peter Bent Brigham Hospital

MONDAY, JANUARY 8

12:00 m.-1:00 p.m. Clinicopathological conference. Peter Bent Brigham Hospital

TUESDAY, JANUARY 9

*12:15-1:15 p.m. Clinicoröntgenological conference. Peter Bent Brigham Hospital

(Notices continued on page xvii)
